

Chapter Two

Partial Derivative

2.1 partial derivatives of function of two variables

Suppose that (x_0, y_0) is a point in the domain of a function $f(x,y)$.

If we fix $y=y_0$ then $f(x, y_0)$ is a function of a variable x alone .

The value of derivative is : $\frac{d}{dx} [f(x, y_0)]$

If we fix $x=x_0$, then $f(x_0,y)$ is a function of a variable y alone.

The value of derivative is : $\frac{d}{dy} [f(x_0, y)]$

If $z= f(x,y)$ and (x_0, y_0) is a point in the domain of f , then the partial derivative of z with respect to x at (x_0, y_0) is :

$$f_x(x_0, y_0) = \frac{d}{dx} [f(x, y_0)]_{x=x_0} = \lim_{x \rightarrow x_0} \frac{f(x, y_0) - f(x_0, y_0)}{x - x_0}$$

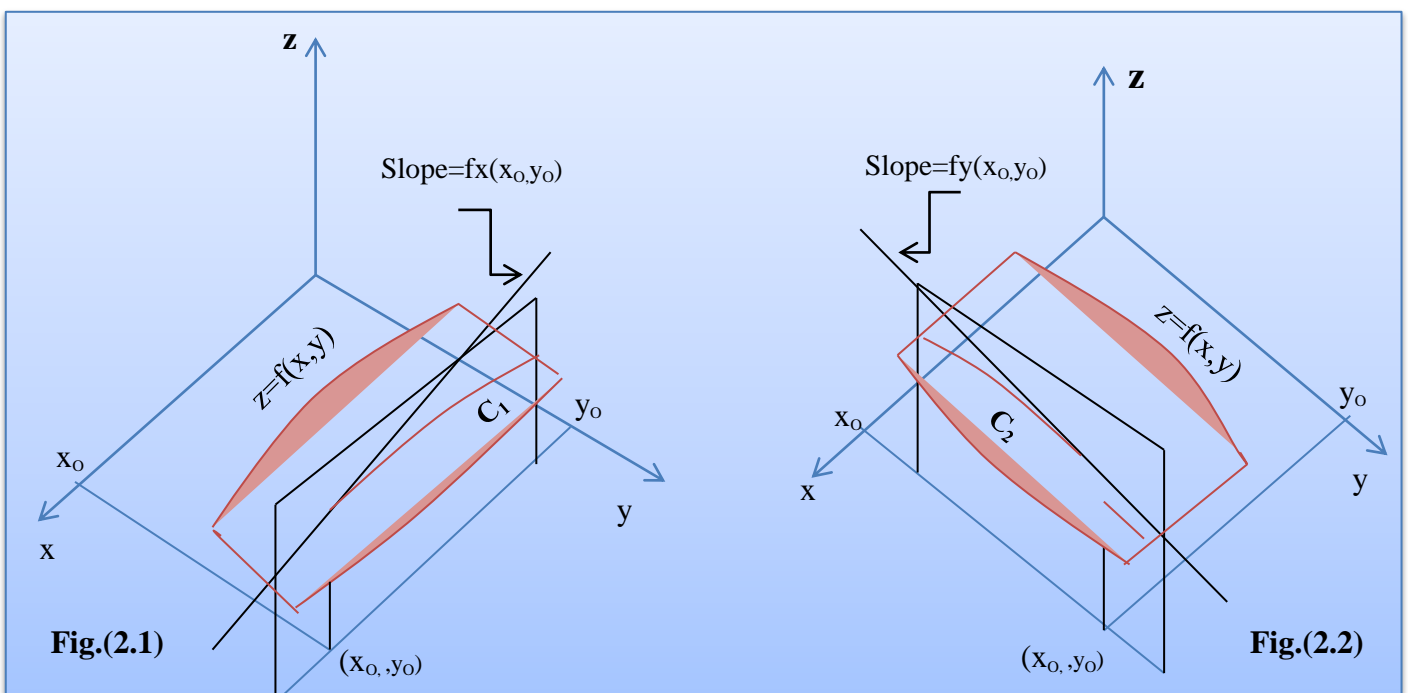

$f_x(x_0, y_0)$ = The slope of the surface $z=f(x,y)$ in the x direction at (x_0, y_0) .

=The rate of change of z with respect to x along the curve C_1 .**Fig.(2.1)**

Similarly... $f_y(x_0, y_0) = \frac{d}{dy} [f(x_0, y)]_{y=y_0} = \lim_{y \rightarrow y_0} \frac{f(x_0, y) - f(x_0, y_0)}{y - y_0}$

$f_y(x_0, y_0)$ = The slope of the surface $z=f(x,y)$ in the y direction at (x_0, y_0)

= The rate of change of z with respect to y along the curve C_2 .**Fig(2.2)**

Slopes and Rates of Change

If $y=f(x)$, then the average rate of change of y with respect to x over the interval $[x_0, x_1]$ is

$$r_{ave} = \frac{f(x_1)-f(x_0)}{x_1-x_0}$$

If $y=f(x)$, then the instantaneous rate of change of y with respect to x when $x=x_0$ is

$$r_{inst} = \lim_{x_1 \rightarrow x_0} \frac{f(x_1)-f(x_0)}{x_1-x_0}$$

$\lim_{x_1 \rightarrow x_0} \frac{f(x_1)-f(x_0)}{x_1-x_0}$ exists , then

The value of this limit is called the *derivative of f at $x=x_0$* and if denoted by $\bar{f}(x_0)$

$$\bar{f}(x_0) = \lim_{x_1 \rightarrow x_0} \frac{f(x_1) - f(x_0)}{x_1 - x_0}$$

$\bar{f}(x_0)$ is the slope of the graph of f at point $p(x_0, f(x_0))$

Example : let $f(x, y) = x^2y + 5y^3$

- 1) Find the slope of the surface $z = f(x, y)$ in the x – direction at the point $(1, -2)$
- 2) Find the slope of the surface $z = f(x, y)$ in the y –direction at the point $(1, -2)$

Solution :

- 1) Differentiating f with respect to x with y held fixed yields

$$f_x(x, y) = 2xy$$

The slope in the x - direction is $f_x(1, -2) = -4$, that is z is decreasing at the rate of 4 unit per unit increase in x .

- 2) Differentiating f with respect to y with x held fixed yields

$$f_y(x, y) = x^2 + 15y^2$$

The slope in the y –direction is $f_y(1, -2) = 61$, that is , z is increasing at the rate of 61 units per unit increase in y .

Example : determined $f_x(1, 3)$ and $f_y(1, 3)$ for the function

$$f(x, y) = 2x^3y^2 + 2y + 4x$$

Solution :

$$f_x(x, y) = \frac{d}{dx} [2x^3y^2 + 2y + 4x] = 6x^2y^2 + 4$$

$$f_x(1, 3) = 6(1)^2(3)^2 + 4 = 58$$

$$f_y(x, y) = \frac{d}{dy} [2x^3y^2 + 2y + 4x] = 4x^3y + 2$$

$$f_y(1, 3) = 4(1)^3(3) + 2 = 14$$

2.2 Partial Derivative notation

If $z = f(x,y)$, then the partial derivatives f_x and f_y are also denoted by the symbols

$$\frac{\partial f}{\partial x}, \frac{\partial z}{\partial x} \text{ and } \frac{\partial f}{\partial y}, \frac{\partial z}{\partial y}$$

Some typical notations for the partial derivatives of $z = f(x,y)$ at a point (x_0, y_0) are

$$\left. \frac{\partial f}{\partial x} \right|_{x=x_0, y=y_0}, \quad \left. \frac{\partial z}{\partial x} \right|_{(x_0, y_0)}, \quad \left. \frac{\partial y}{\partial x} \right|_{(x_0, y_0)}, \quad \frac{\partial f}{\partial x}(x_0, y_0), \quad \frac{\partial z}{\partial x}(x_0, y_0)$$

Example : find $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$ if $z = x^4 \sin(xy^3)$

$$\begin{aligned} \frac{\partial z}{\partial x} &= \frac{\partial}{\partial x} [x^4 \sin(xy^3)] = x^4 \frac{\partial}{\partial x} [\sin(xy^3)] + \sin(xy^3) \frac{\partial}{\partial x} [x^4] \\ &= x^4 \cos(xy^3) * y^3 + \sin(xy^3) * 4x^3 = x^4 y^3 \cos(xy^3) + 4x^3 \sin(xy^3) \end{aligned}$$

$$\begin{aligned} \frac{\partial z}{\partial y} &= \frac{\partial}{\partial y} [x^4 \sin(xy^3)] = x^4 \frac{\partial}{\partial y} [\sin(xy^3)] + \sin(xy^3) \frac{\partial}{\partial y} [x^4] \\ &= x^4 \cos(xy^3) * 3xy^2 + \sin(xy^3) * 0 = 3x^5 y^2 \cos(xy^3) \end{aligned}$$

Note :

The partial derivatives of a function give the instantaneous rates of change of that function in directions parallel to the coordinate .

2.3 Partial Derivatives of functions with more than two variables

For a function $f(x,y,z)$ of three variables, there are three partial derivatives

$$f_x(x, y, z), \quad f_y(x, y, z), \quad f_z(x, y, z)$$

The partial derivative f_x is calculated by holding y and z constant and differentiating with respect to x . For f_y the variables x and z are held constant. If $w = f(x,y,z)$

The three partial derivatives of w can be denoted by

$$\frac{\partial w}{\partial x}, \quad \frac{\partial w}{\partial y}, \quad \text{and} \quad \frac{\partial w}{\partial z}$$

Example :if $w = f(x, y, z) = x^3y^2z^4 + 2xy + z$, then

$$f_x(x, y, z) = 3x^2y^2z^4 + 2y$$

$$f_y(x, y, z) = 2x^3yz^4 + 2x$$

$$f_z(x, y, z) = 4x^3y^2z^3 + 1$$

2.4 Higher – Order Partial Derivatives

The partial derivatives $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$, themselves have partial derivatives. This gives rise to four possible second – order partial derivatives of f , which are defined by :

$$\frac{\partial^2 f}{\partial x^2} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) = f_{xx} \quad \text{differential twice with respect to } x$$

$$\frac{\partial^2 f}{\partial y^2} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial y} \right) = f_{yy} \quad \text{differential twice with respect to } y$$

$$\frac{\partial^2 f}{\partial y \partial x} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} \right) = f_{xy} \quad \text{differential first with respect to } x \text{ and then with respect to } y$$

$$\frac{\partial^2 f}{\partial x \partial y} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right) = f_{yx} \quad \text{differential first with respect to } y \text{ and then with respect to } x$$

The last two cases are called the **mixed second –order partial derivatives** .

Also , the derivatives $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ are called the **first – order partial derivatives**

Some possibilities of third –order , fourth – order are :

$$\frac{\partial^3 f}{\partial x^3} = \frac{\partial}{\partial x} \left(\frac{\partial^2 f}{\partial x^2} \right) = f_{xxx} \quad , \quad \frac{\partial^4 f}{\partial y^4} = \frac{\partial}{\partial y} \left(\frac{\partial^3 f}{\partial y^3} \right) = f_{yyyy}$$

$$\frac{\partial^3 f}{\partial y^2 \partial x} = \frac{\partial}{\partial y} \left(\frac{\partial^2 f}{\partial y \partial x} \right) = f_{xyy}, \quad \frac{\partial^4 f}{\partial y^2 \partial x^2} = \frac{\partial}{\partial y} \left(\frac{\partial^3 f}{\partial y \partial x^2} \right) = f_{xxyy}$$

Example :find the second –order partial derivative of $f(x, y) = x^2y^2 + x^4y$

Solution :

$$\frac{\partial f}{\partial x} = 2xy^3 + 4x^3y \quad \text{and} \quad \frac{\partial f}{\partial y} = 3x^2y^2 + x^4$$

$$\frac{\partial^2 f}{\partial x^2} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) = \frac{\partial}{\partial x} (2xy^3 + 4x^3y) = 2y^3 + 12x^2y = f_{xx}$$

$$\frac{\partial^2 f}{\partial y^2} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right) = \frac{\partial}{\partial y} (3x^2y^2 + x^4) = 6x^2y = f_{yy}$$

$$\frac{\partial^2 f}{\partial x \partial y} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right) = \frac{\partial}{\partial x} (3x^2y^2 + x^4) = 6xy^2 + 4x^3 = f_{yx}$$

$$\frac{\partial^2 f}{\partial y \partial x} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} \right) = \frac{\partial}{\partial y} (2xy^3 + 4x^3y) = 6xy^2 + 4x^3 = f_{xy}$$

Example :let $f(x, y) = y^2e^x + y$ find f_{xyy}

Solution :

$$f_{xyy} = \frac{\partial^3 f}{\partial y^2 \partial x} = \frac{\partial^2}{\partial y^2} \left(\frac{\partial f}{\partial x} \right) = \frac{\partial^2}{\partial y^2} (y^2e^x) = \frac{\partial}{\partial y} (2ye^x) = 2e^x$$
