# ANALYTICAL CHEMISTRY 

## LECTURE-1 <br> BY

Dr. ABBAS HASAN FARIS

## Analytical Chemistry

- ANALYTICAL CHEMISTRY: It is a chemistry branch deals with the study on the identification of material composition and the determination of the amount of each component presented by an expression of concentration directly or indirectly (after separation).
- It is divided in to two main parts:

## 1- QUALITATIVE ANALYSIS:

It is process of many steps that through which material, compounds or elements or elements forming certain material or a mixture of materials can be identified at liquid, gas or solid phases. This process is the first step in analysis.

## 2-QUANTITATIVE ANALYSIS:

It is a process deals with the determination of elements or other components that form the analyzed material (compound or mixture). It tell us what is the amount of the components of the materials or their Components. Quantitative analysis can not be preceded without processing qualitative analysis.

Analytes: Are the components of a sample that • are to be determined.
Matrix: All other constituents in a sample • except for the analytes.

Classifying Analytical Techniques:
1- Classical Techniques
2- Instrument Techniques

## Classical Techniques

- Mass, volume, and charge are the most common signals for classical techniques, and the corresponding techniques are:
-1- Volumetric techniques (Titrimetric analysis): The analyte reacts with a measured volume of reagent of known concentration, in a process called titration.
- 2- Gravimetric techniques: usually involves the selective separation of the analyte by precipitation, followed by the very non-selective measurement of mass (of the precipitate).
-3-Coulometeric techniques.

## INSTRUMENTAL TECHNIQUES

- Determination of materials or their components can be performed using instruments that their measurements of certain properties such as conductivity, turbidity, potentiometry, color, refractive index, absorption at UV or visible region etc...provided these measurements depend on and relate to the concentration of the material or its components directly or indirectly.

## INSTRUMENTAL TECHNIQUES

- 1- Spectroscopic methods:- measuring the interaction between the analyte and electromagnetic radiation (or the production of radiation by an analyte).
- 2- Electroanalytic methods:- measure an electrical property (i.e., potential, current, resistance, amperes, etc.) chemically related to the amount of analyte.
- A - Using of Conductivitimeter to measure the conductivity of sample solution which is changing with variation in the component concentration.
- B - Using of potentiometer to measure the potential of an electrode which is in equilibrium with the sample solution.
- C - Using of UV-visible spectrometer to measure the absorbance of radiation at a wave length that relate to the component directly or to the compound formed by its reaction with a reagent.

## STEPS OF CHEMICAL ANALYSIS:

- There are a general steps for any analysis process, a modifications in these steps depend on nature, size, the accuracy required, availability of reagents chemicals equipment's and apparatus

## - STEP 1: CHOICE OF THE METHOD:

- The selected method should be suitable to the nature of the sample, number of samples and accuracy required. Some samples like archaeological or forensic samples need a nondestructive method to keep the samples without destruction.

## - STEP 2: SAMPLING:

Sampling is a very important criterion. It is the fraction of the material with which he plans to work. It is truly representative the whole of it. If the material is big many samples are selected and collected.

## STEP 3: PREPARING OF LABORATORY SAMPLE:

The field sample is treated to prepare the laboratory sample required for the analysis.

1. Producing a homogenized sample by crashing, grinding and mixing.
2. Decreasing the size of the material sample granules.
3. Turning the sample into a phase and formula can be attacked by reagent.
4. Care should be taken to avoid the interferences or any other factors affecting the estimation such as contamination.

- STEP 4: MEASURE THE QUANTITY OF THE SAMPLE:
- If the sample is solid certain weight of the dried homogenized sample is taken using calibrated balance. If it is liquid certain volume is taken.

## - STEP 5: DISSOLUTION OF THE MEASURED SAMPLE:

- A suitable solvent is selected to dissolve the sample completely and within short time. The sample should not interfere in the analysis. Water is a magic solvent for almost all the inorganic materials and some of the organic materials. Organic materials require organic solvents like alcohols, carbontetrachloride and chloroform. Fusion is used for melting samples do not dissolve in solvents.
- STEP 6: SEPARATION OF THE INTERFERING SUBSTANCES.
- To measure the sample freely from interferences by other components certain steps should be taken such as separation or using masking agents.

## - STEP 7: COMPLETION OF THE ANALYSIS

- This step concern with the measurement of the substance or component under consideration precisely using a suitable method by precipitation or color formation, titration etc.

## - STEP 8: CALCULATIONS AND DATA ANALYSIS:

- From the numeric results obtained by measurements the final result is calculated using the weight of the analyzed sample. The final results may e evaluated by statistic analysis.

## METHODS OF EXPRESSION OF CONCENTRATION

- Concentration:- is a general measurement unit stating the amount of solute present in a known amount of solution.
- concentration $=\frac{\text { amount of solute }}{\text { amount of solution }}$

## - 1- Molarity

Number of grams molecular weight (moles) of solute per liter of solution.

$$
M=\frac{\text { number of moles }}{V(\text { Liter })}
$$

$$
M=\frac{n}{V(\text { Liter })}
$$

$$
M=\frac{\text { number of millimoles }}{V m L}
$$

Units: mole/L, mmole/mL

$$
n=\frac{W t}{M \cdot W t}
$$

$$
M=\frac{W t}{M \cdot W t} \times \frac{1000}{m L}
$$

- Ex: How many grams of 0.125 M AgNO used to prepare 500 ml of its solution.
- ( M.Wt= 169.9 g/mole)
$\cdot M=\frac{W t}{M . W t} \times \frac{1000}{V m L} \Rightarrow 0.125=\frac{W t}{169.9} \times \frac{1000}{500}$
- Wt $=\frac{M \times M . W T \times V m L}{1000}$
$\cdot W t=\frac{0.125 \times 169.9 \times 500}{1000}=10.619 \mathrm{~g}$
- Ex: Calculate the Molarity (M) of solution result from dissolving 20 g of Sodium hydroxide in 2 Litters of solution. $\mathrm{Na}=23,0$ = 16 , H = 1
- $M=\frac{n}{V(\text { Liter })} \quad$ NaOH $M . W t=23+16+1=40 \mathrm{~g} / \mathrm{mole}$
- $n=\frac{W t}{M . W t}=\frac{20}{40}=0.5 \mathrm{~mole} \Rightarrow M=\frac{0.5}{2}=0.25 M$
or: $M=\frac{W t}{M . W t} \times \frac{1000}{m L}$

$$
\Rightarrow M=\frac{20}{40} \times \frac{1000}{2000}=0.25 M
$$

or: $M=\frac{W t}{M \cdot W t} \times \frac{1}{v l}$

$$
\Rightarrow M=\frac{20}{40} \times \frac{1}{2}=0.25 M
$$

- Q: A sample of water is found to contain 0.003 g of lead in a $250 \mathrm{~cm}^{3}$ sample. What is the concentration of lead in ppm? A: $0.003 \times 4 \times 1000=12 \mathrm{ppm}$

## 5. Molarity

- Number of moles per litre
- Most common method of expressing concentration
- $1 \mathrm{M}=1 \mathrm{~mol} /$ litre $=1 \mathrm{~mol} \mathrm{1}^{-1}$
- A 1 Molar solution contains one mole of solute dissolved in 1 litre of solution

Q : A solution is labelled 0.15 M HCl. How many grams of HCl are present in 1 litre?
A: $\mathrm{M}_{\mathrm{r}}$ of $\mathrm{HCl}=36.5 \mathrm{~g}$
1 M solution contains $36.5 \mathrm{~g} / 1$
0.15 M solution $=36.5 \times 0.15=5.475 \mathrm{~g}$

Q : A solution contains $4.9 \mathrm{~g} \mathrm{H}_{2} \mathrm{SO}_{4}$ in $100 \mathrm{~cm}^{3}$.
Calculate the concentration in mol/l.
A: $\mathrm{M}_{\mathrm{r}}$ of $\mathrm{H}_{2} \mathrm{SO}_{4}=98 \mathrm{~g}$
$4.9 \div 98=0.05 \mathrm{~mol}$ in $100 \mathrm{~cm}^{3}$
$0.05 \times 10=0.5 \mathrm{~mol} / 1$

## 2-Normality:

Number of gram equivalent weight of solute per liter of solution

$$
N=\frac{\text { number of equivelant }}{V(\text { Liter })} \quad N=\frac{\text { no. of eq }}{V(\text { Liter })}
$$

no. of eq $=\frac{W t}{E W} \quad$ Wt: weight of solute, EW: equivalent weight of solute

$$
N=\frac{\text { no. of meq }}{V m L} \quad \text { VmL: volume of solution in } \mathrm{mL}
$$

$$
\mathrm{N}=\frac{W t}{E W} \times \frac{1000}{m L} \quad \text { Units: eq/L, eq/mL }
$$

Consequently, the following simple relationship exists between normality and molarity.

$$
N=n \times M
$$

Example 2.1 illustrates the relationship among chemical reactivity, equivalent weight, and normality.

## - Ex: How many grams of 0.2 N Sodium carbonate in $\mathbf{2 5 0}$ ml solution.

## (M.Wt =106g / mole)

$\mathrm{EW}($ salt $)=\frac{\text { M.Wt }}{\text { no.of cations } x \text { oxidation number of cations }}$
$E W(\mathrm{Na} 2 \mathrm{CO} 3)=\frac{106}{2 x 1}=53 \mathrm{~g} / \mathrm{eq}$
$\mathrm{N}=\frac{W t}{E W} \times \frac{1000}{m L}$
$0.2=\frac{W t}{53} \times \frac{1000}{250}$

$$
\Rightarrow \mathrm{Wt}=\frac{0.2 \times 53 \times 250}{1000}=2.650 \mathrm{~g}
$$

- Ex: Calculate the normality ( N ) of solution result from dissolving 0.5 g of
- Cu(OH)2 in 100 mL of distilled water.

$$
\mathrm{Cu}=63.5 \quad \mathrm{O}=16 \quad \mathrm{H}=1
$$

- $\mathrm{Cu}(\mathrm{OH}) 2$ M. wt $=63.5+2 x 16+2 x 1=97.5 g / m o l e$
- eq. wt $($ base $)=\frac{M . W t}{\text { no.of OH ions ready to substituted }}$
- $\frac{97.5}{2}=48.75$
- $\mathrm{N}=\frac{W t}{E W} \times \frac{1000}{m L} \quad \Rightarrow \frac{0.5}{48.75} \times \frac{1000}{100}=0.103 \mathrm{~N}$
- Example: Calculate the analytical and equilibrium molar concentrations of the solute species in an aqueous solution that contains 285 mg of trichloroacetic acid, $\mathrm{Cl}_{3} \mathrm{CCOOH}(163.4 \mathrm{~g} / \mathrm{mol})$, in 10.0 mL (the acid is $73 \%$ ionized in water).
-     - Solution: we calculate the number of moles of $\mathrm{Cl}_{3} \mathrm{CCOOH}$, which we symbolize, as HA, and divide by the volume of the solution, 10.0 mL , or 0.0100 L.
- Therefore,

$$
\begin{aligned}
\text { armount HA }=n_{\mathrm{HA}} & =285 \mathrm{mg} H A \times \frac{1 \mathrm{gHA}}{1000 \mathrm{mg} H A} \times \frac{1 \mathrm{molHA}}{163.4 \mathrm{gHA}} \\
& =1.744 \times 10^{-3} \mathrm{molHA}
\end{aligned}
$$

The molar analytical procentration, GHA, is then

$$
\sigma_{\mathrm{HA}}=\frac{1.744 \times 10^{-3} \mathrm{~mol} \mathrm{HA}}{10.0 \mathrm{mE}} \times \frac{1000 \mathrm{mE}}{1 \mathrm{~L}}=0.174 \frac{\mathrm{~mol} \mathrm{HA}}{\mathrm{~L}}=0.174 \mathrm{M}
$$

In this solution, $73 \%$ of the HA dissociates, giving $H^{+}$and $A^{-}$=

$$
\mathbf{H A} \rightleftharpoons \mathbf{H}^{+}+\mathbf{A}^{-}
$$

The equilibrium concentration of HA is then $27 \%$ of cHA- Thus,

$$
\begin{aligned}
{[H A] } & =0.1 \times(100-73) / 100=0.174 \times 0.27=0.047 \mathrm{~mol} / \mathrm{L} \\
& =0.047 \mathrm{M}
\end{aligned}
$$

The equilibrium concentration of $\mathrm{A}^{-}$is equal to $73 \%$ of the analytical concentration of HA, that is,

$$
\left[A^{-}\right]=\frac{73 \mathrm{~mol} \mathrm{~A}^{-}}{100 \mathrm{~mol} H \mathrm{HA}^{-}} \times 0.174 \frac{\mathrm{~mol} \mathrm{HA}}{\mathrm{~L}}=0.127 \mathrm{M}
$$

Because 1 mole of $\mathrm{H}^{+}$is formed for cach mole of $\mathrm{A}^{-}$, we can also write

$$
\left[\mathrm{H}^{+}\right]=\left[\mathrm{A}^{-}\right]=0.127 \mathrm{M}
$$

and

$$
\sigma_{\mathrm{HA}}=[\mathrm{HA}]+\left[\mathrm{A}^{-}\right]=0.047+0.127=0.174 \mathrm{M}
$$

## - Example: Describe the preparation of 2.00 L of $0.10 \mathrm{M} \mathrm{Na} 2 \mathrm{CO} 3(106 \mathrm{~g} / \mathrm{mol})$ from the solid?

- $\mathrm{mol} \mathrm{Na}_{2} \mathrm{CO}_{3}$ needed $=0.1 \mathrm{~mol} / \mathrm{L} \times 2 \mathrm{~L}=0.2 \mathrm{~mol}$
- mass $\mathrm{Na}_{2} \mathrm{CO}_{3}=0.2 \mathrm{~mol} \times 106 \mathrm{~g} / \mathrm{mol}=21.2 \mathrm{~g}$
- Dissolve 21.2 g of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ in distilled water and dilute to 2 L .

## EXAMPLE 2.1

- Calculate the equivalent weight and normality for a solution of $6.0 \mathrm{M} \mathrm{H}_{3} \mathrm{PO}_{4}$ given the following reactions:
(a) $\mathrm{H}_{3} \mathrm{PO}_{4}(a q)+3 \mathrm{OH}^{-}(a q) \rightleftharpoons \mathrm{PO}_{4}{ }^{3-}(a q)+3 \mathrm{H}_{2} \mathrm{O}(\ell)$
(b) $\mathrm{H}_{3} \mathrm{PO}_{4}(a q)+2 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{HPO}_{4}{ }^{2-}(a q)+2 \mathrm{NH}_{4}{ }^{+}(a q)$
(c) $\mathrm{H}_{3} \mathrm{PO}_{4}(a q)+\mathrm{F}-(a q) \rightleftharpoons \mathrm{H}_{2} \mathrm{PO}_{4}^{-}-(a q)+\mathrm{HF}(a q)$

## sOLUTION

For phosphoric acid, the number of equivalents is the number of $\mathrm{H}^{+}$ions donated to the base. For the reactions in (a), (b), and (c) the number of equivalents are 3,2 , and 1 , respectively. Thus, the calculated equivalent weights and normalities are
(a) $\mathrm{EW}=\frac{\mathrm{FW}}{n}=\frac{97.994}{3}=32.665 \quad \mathrm{~N}=n \times \mathrm{M}=3 \times 6.0=18 \mathrm{~N}$
(b) $\mathrm{EW}=\frac{\mathrm{FW}}{n}=\frac{97.994}{2}=48.997 \quad \mathrm{~N}=n \times \mathrm{M}=2 \times 6.0=12 \mathrm{~N}$
(c) $\mathrm{EW}=\frac{\mathrm{FW}}{n}=\frac{97.994}{1}=97.994 \quad \mathrm{~N}=n \times \mathrm{M}=1 \times 6.0=6.0 \mathrm{~N}$

## 2B. 3 Molality

Molality is used in thermodynamic calculations where a temperature independent unit of concentration is needed. Molarity, formality and normality are based on the volume of solution in which the solute is dissolved. Since density is a temperature dependent property a solution's volume, and thus its molar, formal and normal concentrations, will change as a function of its temperature. By using the solvent's mass in place of its volume, the resulting concentration becomes independent of temperature.

## - 3-Formality

Number of gram formula weight of solute per liter of solution
$F=\frac{\text { number of formula weight }}{V(\text { Liter })}$
$F=\frac{\text { no.of } f \boldsymbol{w}}{V(\text { Liter })}$
no. of $f w=\frac{W t}{f w} \quad W t$ : weight of solute, $f \mathrm{~W}$ : formula weight of solute
$F=\frac{W t}{f w} \times \frac{1000}{V m L} \quad w t$ : weight of solute, fw: formula weight Units: eq/L, eq/mL

## - 4- Percentage Ratio:

A- Weight per Volume Percentage : No. of g of solute in 100 mL of solution
$\% W / V=\frac{W t \text { of solute }}{V \text { mL of solution }} \times 100$
B- Volume Percentage : No. of mL of solute in 100 mL of solution
$\% V / V=\frac{V m L \text { of solute }}{V m L \text { of solution }} \times 100$
C- Weight Percentage : No. of g of solute in 100 g of solution.
$\% W / W=\frac{w t ~ o f ~ s o l u t e}{w t ~ o f ~ s o l u t i o n ~} \times 100$

A concentrated solution of aqueous ammonia is $28.0 \% \mathrm{w} / \mathrm{w} \mathrm{NH}_{3}$ and has a density of $0.899 \mathrm{~g} / \mathrm{mL}$. What is the molar concentration of $\mathrm{NH}_{3}$ in this solution?

## SOLUTION

$$
\frac{28.0 \mathrm{~g} \mathrm{NH}_{3}}{100 \mathrm{~g} \text { solution }} \times \frac{0.899 \mathrm{~g} \text { solution }}{\mathrm{mL} \text { solution }} \times \frac{1 \mathrm{~mole} \mathrm{NH}_{3}}{17.04 \mathrm{~g} \mathrm{NH}_{3}} \times \frac{1000 \mathrm{~mL}}{\text { liter }}=14.8 \mathrm{M}
$$

- The maximum allowed concentration of chloride in a municipal drinking water supply is $2.50 \times 10^{2} \mathrm{ppm} \mathrm{Cl}{ }^{-}$. When the supply of water exceeds this limit, it often has a distinctive salty taste. What is this concentration in moles $\mathrm{Cl}^{-} /$liter?

SOLUTION

$$
\frac{2.50 \times 10^{2} \mathrm{mg} \mathrm{Cl}^{-}}{\mathrm{L}} \times \frac{1 \mathrm{~g}}{1000 \mathrm{mg}} \times \frac{1 \mathrm{~mole} \mathrm{Cl}^{-}}{35.453 \mathrm{~g} \mathrm{Cl}^{-}}=7.05 \times 10^{-3} \mathrm{M}
$$

- Ex: Calculate the percentage ratio for solution result from dissolving 5 g of Sodium hydroxide in 0.25 L of solution
- $\% W / V=\frac{W t \text { of solute }}{V \text { mL of solution }} \times 100=\frac{5}{250} \times 100=2 \%$
- Ex: Calculate the percentage ratio for solution result from addition of 200 mL of Methanol to 400 mL distilled water.
- $\% V / V=\frac{V m L \text { of solute }}{V m L \text { of solution }} \times 100=\frac{200}{200+400} \times 100=33.33 \%$
- Ex: Calculate the No. of g of glucose solution in 800 mL industrial solution, if its percentage ratio is $15 \%$
- $\% W / V=\frac{W t \text { of solute }}{V \text { mL of solution }} \times 100$
$\cdot \% 15=\frac{\text { Wt of glucose }}{800} \times 100=120 \mathrm{~g}$
- Gram (g) = 1000 Milligram (mg)
- Milligram (mg) =1000 Microgram ( $\mu \mathrm{g}$ )
- Microgram ( $\mu \mathrm{g}$ ) = 1000 Nanogram(ng)
- Liter (L) = 1000 Milliliter (mL)
- Milliliter (mL) = 1000 Microliter( $\mu \mathrm{L}$ )
- $\operatorname{Mic}$ croliter $(\mu \mathrm{L})=1000$ Nanoliter( nL )
- 5. Parts per thousandth (ppt)
- ppt $=\frac{W t \text { of solute }}{w t \text { of } \text { solution }} \times 10^{3}$

$$
=\frac{W t(m g)}{w t(g)}=\frac{W t(g)}{w t(k g)}
$$

- 6-Parts per million (ppm)
- ppm $=\frac{W t \text { of solute }}{w t \text { of solution }} \times 10^{6}$

$$
==\frac{W t(m g)}{w t(k g)}
$$

- 7-Parts per billion (ppb)
- ppb $=\frac{\text { Wt of solute }}{\text { wt of solution }} \times 10^{9}$

$$
=\frac{W t(n g)}{w t(g)}=\frac{W t(u g)}{w t(g)}
$$

$$
\cdot \frac{W t(u g)}{w t(g)}
$$

## Common Units for Expressing Trace Concentrations

| Unit | Abbreviation | $\mathrm{wt} / \mathrm{wt}$ | $\mathrm{wt} / \mathrm{vol}$ | $\mathrm{vol} / \mathrm{vol}$ |
| :--- | :---: | :---: | :--- | :--- |
| Parts per million | ppm | $\mathrm{mg} / \mathrm{kg}$ | $\mathrm{mg} / \mathrm{L}$ | $\mu \mathrm{L} / \mathrm{L}$ |
| $\left(1 \mathrm{ppm}=10^{-4} \%\right)$ |  | $\mu \mathrm{g} / \mathrm{g}$ | $\mu \mathrm{g} / \mathrm{mL}$ | $\mathrm{nL} / \mathrm{mL}$ |
| Parts per billion | ppb | $\mu \mathrm{g} / \mathrm{kg}$ | $\mu \mathrm{g} / \mathrm{L}$ | $\mathrm{nL} / \mathrm{L}$ |
| $\left(1 \mathrm{ppb}=10^{-7} \%=10^{-3} \mathrm{ppm}\right)$ |  | $\mathrm{ng} / \mathrm{g}$ | $\mathrm{ng} / \mathrm{mL}$ | $\mathrm{pL} / \mathrm{mL}^{a}$ |
| Milligram percent | $\mathrm{mg} \%$ | $\mathrm{mg} / 100 \mathrm{~g}$ | $\mathrm{mg} / 100 \mathrm{~mL}$ |  |

${ }^{a}{ }_{\mathrm{p}} \mathrm{L}=$ picoliter $=10^{-12} \mathrm{~L}$.

- Example :-A 2.6 g sample of plant tissue was analyzed and found to contain 3.6 ug zinc, what is the concentration of zinc in the plant in ppm? in ppb?
- Ppm $=\frac{W t(u g)}{w t(g)}=\frac{3.6(u g)}{2.6(g)}=1.4 \frac{u g}{g}=1.4 \mathrm{ppm}$
$-\mathrm{Ppb}=\frac{W t(n g)}{w t(g)}=\frac{3.6 \times 10^{3}(n g)}{2.6(g)}=1.4 \times 10^{3} \frac{\mathrm{ng}}{\mathrm{g}}=1400 \mathrm{ppb}$

## Table 2.4 Common Units for Reporting Concentration

| Name | Units ${ }^{\text {a }}$ | Symbol |
| :---: | :---: | :---: |
| molarity | moles solute liters solution. | M |
| formality | number FVVs solute liters solution | F |
| normality | $\frac{\text { number EWV solute }}{\text { liters solution }}$ | N |
| molality | moles solute kg solvent | $m$ |
| weight \% | $\frac{9 \text { solute }}{100 \mathrm{~g} \text { solution }}$ | \% w/w |
| volume \% | mL solute $\overline{100 \mathrm{~mL} \text { solution }}$ | \% V/ |
| weight-to-volume \% parts per million | $\frac{\mathrm{g} \text { solute }}{100 \mathrm{~mL} \text { solution }} \begin{gathered} \mathrm{g} \text { solute } \end{gathered}$ | $\% \mathrm{w} / \mathrm{v}$ ppm |
| parts per billion | $10^{6} \mathrm{~g}$ solution 9 solute <br> $10^{9}$ g solution | ppb |

$a \mathbb{F N}=$ formula weight; $E W=$ equivalent weight.

## Concentration of Solutions

Remember:

- Solution - A mixture of a solute and a solvent
- Solvent - The liquid in which the solute is dissolved
- Solute - The substance that is dissolved in the solvent
- Dilute Solution - contains a small amount of solute per solvent
- Concentrated Solution - contains a large amount of solute per solvent
- Concentration - the amount of solute that is dissolved in a specific volume of solution
- In some solutions concentration can be indicated by colour intensity.
- The less intense the colour - dilute solution
- The more intense the colour - concentrated solution

## - Dilution

-     - Dilute solutions can be prepared from concentrated solutions. A volume of the concentrated solution is transferred to a fresh vessel and diluted to the desired final volume. The number of moles of reagent in V liters containing M moles per liter is the product $\mathbf{M} . \mathbf{V}=\mathrm{mol} / \mathrm{L}$. L , so we equate the number of moles in the concentrated (conc) and dilute (dil) solutions:

## - •Dilution Law:

- (Mconc x V conc $)=($ Mdil $x$ Vdil)
- ( N conc x V conc ) = (Ndil x Vdil)
- We often must prepare to dilute solutions from more concentrated stock solutions. For example, we may prepare a dilute HCL solution from concentrated HCL to be used for titration. Or, we may have a stock standard solution from which we wish to prepare a series of more dilute standards. The millimoles of stock solution taken for dilution will be identical to the millimoles in the final diluted solution.
- Ex: Calculate the normality (N) of solution result from dilution 100 mL of 0.25 N Nitric Acid to 250 mL .
- N1V1 = N2V2
- $0.25 \times 100=\mathrm{N} 2 \times 250 \quad \Rightarrow \mathrm{~N} 2=0.1 \mathrm{~N}$
- Example:- You wish to prepare a calibration curve for the spectrophotometric determination of permanganate. You have a stock 0.100 M solution of $\mathrm{KMnO4}$ and a series of 100 mL volumetric flasks. What volumes of the stock solution will you have to pipet into the flasks to prepare standards of $1.00,2.00,5.00$, and $10.0 \times 10^{-3} \mathrm{M} \mathrm{KMnO4}$ solutions.
- Solution-1: $1.0 \times 10^{-3} \mathrm{M}$
- 

$(\mathrm{M} 1 \times \mathrm{V} 1)$ conc. $=(\mathbf{M} 2 \times \mathrm{V} 2)$ dilu.

- 0.1 ( $\mathrm{mmol} / \mathrm{mL}$ ) $\times$ V1 $=1.0 \times 10^{-3}(\mathrm{mmol} / \mathrm{mL}) \times 100 \mathrm{~mL}$
- V1 = 1.0 mL stock solution (conc. ),Also to prepare $2.0,5.0,10.0 \times 10^{-3} \mathrm{M}$
- Example: Describe how you would prepare the following three solutions: (a) 500 mL of approximately 0.20 M NaOH using solid NaOH ; (b) 1 L of 150.0 $\mathrm{ppm} \mathrm{Cu}{ }^{2+}$ using Cu metal; and (c) 2 L of $4 \% \mathrm{v} / \mathrm{v}$ acetic acid using concentrated glacial acetic acid.
-     - Solution:
- (a) Since the concentration only needs to be known to two significant figures, the mass of NaOH and volume of solution do not need to be measured exactly. The desired mass of NaOH is
- $M=\frac{W t}{M \cdot W t} \times \frac{\mathbf{1 0 0 0}}{m L}$
- $0.20 \mathrm{~mol} / \mathrm{L}=\frac{W \boldsymbol{t}}{\mathbf{4 0 g} / \boldsymbol{m o l}} \times \frac{\mathbf{1 0 0 0}}{\mathbf{5 0 0 \boldsymbol { m L }}}=4.0 \mathrm{~g}$
- To prepare the solution we place 4.0 g of NaOH , in a bottle or beaker and add
- approximately 500 mL of water.
- (b) Since the concentration of $\mathrm{Cu}^{2+}$ needs to be exact, the mass of Cu metal and the final solution volume must be measured exactly. The desired mass of Cu metal is
$\cdot w t=\frac{150 \mathrm{mg}}{L} \times 1.000 L=150.0 \mathrm{mg}=0.1500 \mathrm{~g}$
- To prepare the solution we measure out exactly 0.1500 g of Cu into a small beaker. To dissolve the Cu we add a small portion of concentrated HNO3 and gently heat until it completely dissolves. The resulting solution is poured into a 1 L volumetric flask. The beaker is rinsed repeatedly with small portions of water, which are added to the volumetric flask.
- (c) The concentration of this solution is only approximate, so volumes do not need to be measured exactly. The necessary volume of glacial acetic acid is
$\frac{4.0 \mathrm{~mL} \text { of } \mathrm{CH} 3 \mathrm{COOH}}{100 \mathrm{~mL}} \times 2000 \mathrm{~mL}=800 \mathrm{~mL} \mathrm{CH} 3 \mathrm{COOH}$

To prepare the solution we use a graduated cylinder to transfer 80 mL of glacial acetic acid to a container that holds approximately 2 L , and we then add sufficient water to bring the solution to the desired volume.

- Stock solution: A solution of known concentration from which other solutions are prepared. Quantitative transfer: The process of moving a sample from one container to another in a manner that ensures all material is transferred.
- • Example: The molarity of "concentrated" HCl is approximately 12.1 M . How many milliliters of this reagent should be diluted to 1.000 L to make 0.100 M HCl ?
-     - Solution: The dilution formula handles this problem directly:
- $\mathbf{M}$ conc. Vconc $=\mathbf{M}$ dil. Vdil
- (12.1 M). $(x \mathrm{~mL})=(0.100 \mathrm{M}) .(1000 \mathrm{~mL}) \rightarrow x=8.26 \mathrm{~mL}$
- To make 0.100 M HCl , we would dilute 8.26 mL of concentrated HCl up to 1.000 L . The concentration will not be exactly 0.100 M , because the reagent is not exactly $12.1 \mathbf{M}$. A table inside the cover of this book gives volumes of common reagents required to make 1.0 M solutions.

## Chemical equilibrium

In a chemical reaction, chemical equilibrium is the state in which both the reactants and products are present in concentrations which have no further change with time, so that there is no observable change in the properties of the system.

A reaction is in chemical equilibrium when the rate of the forward reaction equals the rate of the reverse reaction.

- Chemical Reactions Divided into:
- 1- Irreversible Reactions:
- A chemical reaction that can occur in one direction reactions, so that the reactants are completely consumed in the reaction and shown by one arrow.

$$
\mathrm{HCl}+\mathrm{NaOH} \longrightarrow \mathrm{NaCl}+\mathrm{H}_{2} \mathrm{O}
$$

- 2- Reversible Reactions:
- A chemical reaction that can occur in both directions (the forward and backward directions), so that the reactants are incompletely consumed in the reaction and shown by two arrows
$\mathrm{CH}_{3} \mathrm{COOH}+\mathrm{NaOH} \rightleftarrows \mathrm{CH}_{3} \mathrm{COONa}+\mathrm{H}_{2} \mathrm{O}$
- Most of the reactions that are useful for chemical analysis proceed rapidly to a state of chemical equilibrium in which reactants and products exist in constant ratios. The knowledge of this ratio permits the chemists to decide whether the reaction is suitable for chemical analysis or not. Equilibrium constant expressions are algebraic equations that relate to the concentrations of reactants or products.

## Volumetric analysis (titration analysis)

- These are the most useful and accurate analytical techniques, especially for millimole amounts of analyte. They are rapid and can be automated, and they can be applied to smaller amounts of analyte when combined with a sensitive instrumental technique for detecting the completion of the titration reaction, for example, pH measurement. In a titration, the test substance (analyte) in reacts with a reagent added from a burette as a solution of known concentration. This is referred to as a standard solution and is called the titrant. The volume of titrant required to just completely react with the analyte is measured. Since we know the concentration as well as the reaction between the analyte and the reagent, we can calculate the amount of analyte.
- Classification of volumetric or titration methods:-
- (1) Neutralization (acid-base) titrations: Many compounds, both inorganic and organic, are either acids or bases that can be titrated with a standard solution of a strong base or a strong acid. The endpoint of these titrations is easy to detect, either by means of an indicator or by following the change in pH with a pH meter.
- (2) Precipitation titrations: In the case of precipitation, the titrant forms an insoluble product with the analyte. An example is the titration of chloride ions with silver nitrate solution to form a silver chloride precipitate.
- (3) Complexometric titrations (sometimes chelatometry) is a form of volumetric analysis in which the formation of a colored complex is used to indicate the end point of a titration. Complexometric titrations are particularly useful for the determination of a mixture of different metal ions in a solution.
- (4) Reduction-Oxidation titrations: These (redox) titrations involve the titration of an oxidizing agent with a reducing agent or vice versa. An oxidizing agent gains electrons and a reducing agent loses electrons in a reaction between them.

## - p-Functions:

- Scientists frequently express the concentration of a species in terms of its $p$ function or $p$-value. The $p$-value is the negative logarithm (to the base 10) of the molar concentration of that species. Thus, for species $X$,

$$
\text { - } \mathrm{pX}=-\log [\mathrm{X}]
$$

- As shown by the following examples, $p$-values offer the advantage of allowing concentrations that vary over ten or more orders of magnitude to be expressed in terms of small positive numbers.
- Example : Calculate the p -value for each ion in a solution that is $2.00 \times 10^{-3} \mathrm{M}$ in NaCl and $5.4 \times 10^{-4} \mathrm{M}$ in HCl .
- Solution

$$
\begin{aligned}
& \mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]=-\log \left(5.4 \times 10^{-4}\right)=3.27 \\
& \mathrm{pNa}=-\log \left(2.00 \times 10^{-3}\right)=-\log 2.00 \times 10^{-3}=2.699 \\
& {[\mathrm{Cl}-]=2.00 \times 10^{-3} \mathrm{M}+5.4 \times 10^{-4} \mathrm{M} } \\
&=2.00 \times 10^{-3} \mathrm{M}+0.54 \times 10^{-3} \mathrm{M}=2.54 \times 10^{-3} \mathrm{M} \\
& \mathrm{pCl}=-\log 2.54 \times 10^{-3} \mathrm{M}=2.595
\end{aligned}
$$

- Example: Calculate the molar concentration of $\mathrm{Ag}^{+}$in a solution that has a pAg of 6.372.
- Solution:
- $\mathrm{pAg}=-\log \left[\mathrm{Ag}^{+}\right]=6.372, \log \left[\mathrm{Ag}^{+}\right]=-6.372,\left[\mathrm{Ag}^{+}\right]=4.246 \times 10^{-7}=4.25 \times 10^{-7}$
- Materials in its aquase solution classified into two types:
- Electrolytes and non Electrolytes
- All substances that dissociate in water into ions are called electrolytes or ionic substance, those do not dissociate are termed non-electrolytes or nonionic substance.
-     - Aqueous solutions of electrolytes conduct an electric currant, but those of non- electrolytes do not. Electrolytes are classified as Strong or Weak.
- A. Strong Electrolyte materials
- Materials that totally ionized in their aqueous solutions are called strong electrolytes. These electrolytes are good electricity conductors, high solubility, such as strong acids and bases.

$$
\begin{aligned}
\cdot \mathrm{HCl} & \mathrm{H}^{+}+\mathrm{Cl}^{-} \\
\cdot \mathrm{NaOH} & \mathrm{Na}^{+}+\mathrm{OH}^{-} \\
\cdot \mathrm{Ca}(\mathrm{OH})_{2} \longrightarrow & \mathrm{Ca}^{2+}+2 \mathrm{OH}^{-} \\
\cdot \mathrm{NaCl} & \mathrm{Na}^{+}+\mathrm{Cl}^{-}
\end{aligned}
$$

## - B. Weak electrolyte materials

- Materials that partially ionized in their aqueous solutions, reaching ionic equilibrium called weak electrolytes. These electrolytes are weak electricity conductors such as weak acids and bases.

$$
\begin{aligned}
\cdot \mathrm{HCN} & \rightleftarrows \mathrm{H}++\mathrm{CN}^{-} \\
\cdot \mathrm{CH}_{3} \mathrm{COOH} & \rightleftarrows \mathrm{CH}_{3} \mathrm{COO}^{-}+\mathrm{H}^{+} \\
\cdot \mathrm{NH}_{4} \mathrm{OH} & \rightleftarrows \mathrm{NH}_{4}^{+}+\mathrm{OH}^{-}
\end{aligned}
$$

- The dissociation or ionization of weak electrolytes is quantitatively described by equilibrium constant. Suppose the dissociation of $A B$.

$$
\cdot A B \rightleftharpoons A+B
$$

- The equilibrium constant Ke of the dissociation is generally written as:

$$
[\mathrm{A}][\mathrm{B}]
$$

- Ke = -------------
- [AB]

## - NON ELECTROLYTE MATERIALS

- These are the materials that do not release any ions in their aqueous solutions such as ethanol.
- $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH} \rightarrow \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$
- Glucose $\rightarrow$ Glucose

## - ACIDS AND BASES

- 1.Arrhenius concept
- Acid is a material that ionized in water to give hydrogen ion.
- Base is a material that ionized in water to give hydroxide ion.

$$
\cdot \mathrm{HCl} \rightarrow \mathrm{H}++\mathrm{Cl}^{-}, \mathrm{NaOH} \rightarrow \mathrm{Na}^{+}+\mathrm{OH}^{-}
$$

- 2.Bronsted and Lowry concept
- Acid is any substance that is capable of donating proton wherase base is any substance can accept a proten.
- Acid $\rightarrow$ base + proton
- $\mathrm{CH}_{3} \mathrm{COOH}+\mathrm{H}_{2} \mathrm{O} \rightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}+\mathrm{H}_{3} \mathrm{O}^{+}$
acid-1 base-2 base-1 acid-2

- water is amphprotic solvent because it exhibits both acidic and basic properties.
- After an acid has donate a proton the species that remains is capable of accepting proton to reform the original acid then every acid is paired with its corresponding base which is called as conjugate base.

## - ION PRODUCT CONSTANT OF WATER

## (Equilibrium Constant)

Aqueous solutions contain small amount of hydronium ion $\mathrm{H}_{3} \mathrm{O}^{+}$and hydroxide ion $\mathrm{OH}^{-}$

$$
2 \mathrm{H}_{2} \mathrm{O} \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-}
$$

Water dissociates to $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ions in aqueous solutions which are strongly contacted to water molecules. Applying mass product law gives the following equation.

$$
k=\frac{\left[\mathrm{H}_{3} \mathrm{O}+\right][\mathrm{OH}-]}{\left[\mathrm{H}_{2} \mathrm{O}\right]_{2}}
$$

The concentration of water is enormous (each one liter of water equal to $55.5 \mathrm{M})$ when compared with the concentration of hydrogen and hydroxide ions. As consequence water concentration can be considered as a constant.

- $\mathrm{Kw}=\left[\mathrm{H}_{3} \mathrm{O}+\right][\mathrm{OH}-]$ or $\mathrm{Kw}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]$
$\cdot \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{H}^{+}+\mathrm{OH}^{-}$
- $\mathrm{Kw}=\left[\mathrm{H}^{+}\right]$. $\left[\mathrm{OH}^{-}\right]$
- Kw = $1.0 \times 10^{-14} \mathrm{~mole} / \mathrm{L}$
- $[\mathrm{H}+]$. [ $\mathrm{OH}-]=\mathrm{K}\left[\mathrm{H}_{2} \mathrm{O}\right]=\mathrm{Kw}$ (ion product constant of water) by using water concentration as one, Kw approximation value is:
- $1.01 \times 10^{-14}$ or $1.0 \times 10^{-14}$ at $25{ }^{\circ} \mathrm{C}$. Kw increasing with the increase in temperature (at $50^{\circ} \mathrm{C}=5.47 \times 10^{-14}$ and at $100^{\circ} \mathrm{C}=49 \times 10^{-14}$ ).
- $\mathrm{Kw}=$ ion product constant of water $=\left[\mathrm{H}^{+}\right][\mathrm{OH}-]=1.0 \times 10^{-14}$
- in case of pure water.

$$
\begin{gathered}
\cdot\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right] \\
\cdot\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]=10^{-7} \mathrm{~mole} / \mathrm{L}=\mathrm{M}
\end{gathered}
$$

- By taking the logarithm of this equation
- Kw= [H+] [OH-]
- $-\log \mathrm{Kw}=-\log \left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]$
-     - $\log \mathrm{Kw}=-\log \left[\mathrm{H}^{+}\right]-\log \left[\mathrm{OH}^{-}\right]$
- $\mathrm{pKw}=\mathrm{pH}+\mathrm{pOH}=14$
- if $\mathrm{pH}<7$ then the solution acidic.
- if $\mathrm{pH}>7$ then the solution is basic.
- If $\mathrm{pH}=7$ then the solution is equilibrium.

Figure 6.2: Scale showing the pH value for representative solutions. Milk of Magnesia is a saturated solution of $\mathrm{Mg}(\mathrm{OH})_{2}$.

- Ex2: Calculate the pH and pOH values of a solution in which the hydronium ion concentration is $2.0 \times 10^{-3} \mathrm{M}$.
- $\left[\mathrm{H}^{+}\right]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=2.0 \times 10^{-3} \mathrm{~mole} / \mathrm{L}$
$\cdot \mathrm{pH}=-\log [\mathrm{H}]=-\log \left[2.0 \times 10^{-3}\right]$
- $\quad 2.699$
- $\mathrm{pOH}=14-\mathrm{pH}=14-2.699=11.301$

## - EQUILIBRIUM CONSTANTS FOR PAIR ACIDS AND BASES

- Calculation of hydronium and hydroxide ions for strong, acids and bases and weak acids and bases.
- 1-Strong acids
- The strong Acids will completely ionize in its aqueous solution, and shown by one arrow.
$\cdot \mathrm{HCl} \longrightarrow \mathrm{H}^{+}+\mathrm{Cl}^{-} \quad\left[\mathrm{H}^{+}\right]=[\mathrm{HCl}]$
- Ex. Calculate $[\mathrm{H}+]$ and pH of 0.01 M HCl solution

| - | HCl | $\mathrm{H}++$Cl <br> - before ionization <br> - after ionization 0.01 | 0 | 0 |
| :--- | :---: | :--- | :---: | :---: |
| - | 0 | 0.01 | 0.01 |  |

- $[\mathrm{H}+]=0.01 \mathrm{M}$
- $\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]=-\log 0.01=2$
- Ex: Calculate pH and pOH for $0.15 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$
- before ionization
- after ionization $\mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow 2 \mathrm{H}^{+}+\mathrm{SO}^{4-}$
- $\left[\mathrm{H}^{+}\right]=2 \times 0.15=0.3 \mathrm{M}$
- $\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]=-\log 0.3=0.523$
- $\mathrm{Kw}=\mathrm{PH}+\mathrm{pOH}=14$
- $\mathrm{pOH}=14-0.523=13.477$

## - 2- Week acids

- The Weak Acids will incompletely ionize (partial ionization) in its aqueous solution, and shown by two reverse arrows. So lonic equilibrium in is occurring.

$$
\mathrm{CH}_{3} \mathrm{COOH}+\mathrm{H}_{2} \mathrm{O} \leftrightharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{CH}_{3} \mathrm{COO}^{-}
$$

$k a=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{CH} \mathrm{COO}^{-}\right]}{[\mathrm{CH} \mathrm{COOH}]\left[\mathrm{H}_{2} \mathrm{O}\right]}$

Ka is a reaction between the ionized part of the acid and the unionized part of the acid, Ka is a constant provided temperature and pressure are constant, called acid ionization or dissociation constant.
$k b=\frac{K w}{K a}$ for Conjugate Base

- Ex. Calculate $\left[\mathrm{H}^{+}\right]$of $0.1 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ at $25^{\circ} \mathrm{C}\left(\mathrm{Ka}=1.8 \times 10^{-5}\right)$
$\mathrm{CH}_{3} \mathrm{COOH}$
Before ionization 0.1
After ionization 0.1 - x
$\mathrm{CH}_{3} \mathrm{COO}-+\mathrm{H}^{+}$

| 0 | 0 |
| :---: | :---: |
| $x$ | $x$ |

$$
\begin{aligned}
& k a=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]} \\
& \mathrm{Ka}=1.8 \times 10^{-5}=\frac{x . x}{0.1-x}
\end{aligned}
$$

$1.8 \times 10^{-5}=\frac{x 2}{0.1} \quad \mathrm{X}$ is small value and hence it is neglected

$$
x 2=1.8 \times 10^{-6} \quad \text { so } \mathrm{x}=\sqrt{1.8 \times 10-6}
$$

$$
x=1.342 \times 10^{-3} \mathrm{~mole} / \mathrm{L}
$$

## CALCULATION OF HYDROXID ION CONCENTRATION

1. Strong bases

The strong Bases will completely ionize in its aqueous solution. and shown by one arrow.
$\mathrm{NaOH} \rightarrow \mathrm{Na}^{+}+\mathrm{OH}^{-}$
$\mathrm{Ca}(\mathrm{OH})_{2} \rightarrow \mathrm{Ca}^{2+}+2 \mathrm{OH}^{-}$
Ex 1: Calculate the hydronium and hydroxide ion concentrations in
0.2 M aqueous NaOH solution?
$\mathrm{NaOH} \rightarrow \mathrm{Na}^{+}+\mathrm{OH}^{-}$
$\begin{array}{lll}0.2 & 0 & 0 \\ 0 & 0.2 & 0.2\end{array}$
$[\mathrm{OH}-]=0.2 \mathrm{M}$
$\left[\mathrm{H}^{+}\right]=\frac{K w}{[\mathrm{OH}]}=\frac{1 \times 10^{-14}}{0.2}=5 \times 10^{-14}$

- Q: Calculate pOH and pH for $0.15 \mathrm{M} \mathrm{Ca}(\mathrm{OH})_{2}$
- (homework)
- 2. Week bases:
- The Weak Bases will incompletely ionize (partial ionization) in its aqueous solution, shown by two arrows. So the Ionic equilibrium is occurring.
$\begin{array}{llll}\bullet & \mathrm{NH}_{3}+\mathrm{H}_{2} \mathrm{O} & \rightleftarrows & \mathrm{NH}_{4} \mathrm{OH} \\ \text { - } k b=\frac{\left[\mathrm{NH}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{4} \mathrm{OH}\right]} & \text { base } & & \mathrm{NH}^{4+}+\mathrm{OH}^{-} \\ \text {Conjugate Acid }\end{array}$
- $\mathrm{POH}=-\log [\mathrm{OH}] \mathrm{Kb}$ is base ionization constant
- $k a=\frac{K w}{K b} \quad$ for Conjugate Acid
- Ex: Calculate $\left[\mathrm{OH}^{-}\right], \mathrm{pH}$ and pOH of 0.1 M ammonia solution at $25^{\circ} \mathrm{C}$ if $\mathrm{Kb}=1.8 \times 10^{-5}$.
- $\mathrm{NH}_{4} \mathrm{OH} \underset{+{ }^{-}}{\rightleftarrows} \mathrm{NH}^{4+}+\mathrm{OH}^{-}$
- $k b=\frac{\left[\mathrm{NH}^{4}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{4} \mathrm{OH}\right]}$
- Before ionization

| $\mathrm{NH}_{4} \mathrm{OH}$ | $\mathrm{NH}^{4+}+\mathrm{OH}^{-}$ |  |
| :---: | :---: | :---: |
| 0.1 M | zero | zero |
| $0.1-x$ | $x$ | $x$ |

- After ionization
- $k b=\frac{x . x}{0.1-x}=1.8 \times 10^{-5}$
- $\mathrm{X}=\left[\mathrm{OH}^{-}\right]=1.342 \times 10^{-3}$
- $\mathrm{pOH}=-\log [\mathrm{OH}-]=-\log 1.342 \times 10^{-3}=2.872$
- $\mathrm{pH}=14-\mathrm{pOH}=14-2.872=11.128$
- Ex: Calculate $[\mathrm{H}+], \mathrm{pH}$ and pOH of 0.001 M Acetic acid solution at 25 oC if $\mathrm{Ka}=1.8 \times 10-5$.
- $\mathrm{CH}_{3} \mathrm{COOH} \rightleftarrows \mathrm{CH}_{3} \mathrm{COO}^{-}+\mathrm{H}^{+}$
- $\left.k a=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right][\mathrm{CH} \mathrm{COO}}{}{ }^{-}\right] ~\left[\mathrm{CH}_{3} \mathrm{COOH}\right] \quad$

| Before ionization | 0.001 | zero | zero |
| :--- | :--- | :--- | :--- |
| After ionization | $0.001-\mathrm{x}$ | x | x |

$$
\begin{aligned}
& 1.8 \times 10^{-5}=\frac{x . x}{0.001-x}=1.8 \times 10^{-5} \quad \mathrm{x} \text { is ignored } \\
& \begin{aligned}
& 1.8 \times 10^{-5}=\frac{x 2}{0.001} \quad \text { So } \mathrm{X}^{2}=1.8 \times 10^{-5} \times 0.001=1.8 \times 10^{-8} \\
& \mathrm{x}=2.621 \times 10^{-4}
\end{aligned} \\
& \begin{aligned}
& \mathrm{pH}=-\log [\mathrm{H}]=-\log 2.621 \times 10^{-4} \\
&=2.582
\end{aligned} \\
& \begin{aligned}
\mathrm{pOH} & =14-\mathrm{pH} \\
\quad= & 14-2.582=11.418
\end{aligned}
\end{aligned}
$$

## Classification of solutions

Solutions are classified into:
According to the concentration of solute in solution as follows;

1. Saturated solution: the solution in which the solute is in a dynamic equilibrium state with a solution at a certain temperature. i.e. dissolve the amount of solute= amount precipitated of it. The concentration of saturated solution at a certain temperature is represented by the solubility of the solute in a solvent at that temperature. e.g. $37 \mathrm{~g} \mathrm{NaCl} / 100 \mathrm{~mL} \mathrm{H} 2 \mathrm{O}$ at $0^{\circ} \mathrm{C}$.
2. Unsaturated solution: the solution in which the amount of solute is less than is needed for saturation, thus, no dynamic equilibrium exists between the solute and solvent e.g. 20 g of NaCl in 100 mL of water at $0^{\circ} \mathrm{C}$.

3- Supersaturated solutions: the solutions that contain more solute than ordinary required for saturation, at $0^{\circ} \mathrm{C}$. Sodium acetate dissolves in water to extent of $119 \mathrm{~g} / 100 \mathrm{~mL}$, but its solubility increases with increasing temperature.

## Solubility of precipitates

- Solubility is the amount of solute needed to give a saturated solution with a given amount of solvent. Thus, the solubility of NaCl in water at $0^{\circ} \mathrm{C}$ is $37 \mathrm{~g} / 100 \mathrm{~mL}$. Usually solute's solubility changes with temperature. For example at $100^{\circ} \mathrm{C}$ the solubility of NaCl is $39.1 \mathrm{~g} / 100 \mathrm{~mL}$ of $\mathrm{H}_{2} \mathrm{O}$.this means that we should always specify the temperature when stating the solubility.
- Reactions that yield products of limited solubility find application in three important analytical processes:
- 1. The separation of an analyte as a precipitate from soluble substances that would otherwise interfere with ultimate measurement.
- 2. Gravimetric analysis, in which the precipitate is formed whose weight is chemically related to the amount of analyte.
- 3. Titrimetric analysis, based on the determination of volume of a standard reagent required precipitating the analyte essentially completely.
- The success of each of these applications requires that the solids produced have a relatively low solubility, be reasonably pure, and have a suitable particle size.

## PRECIPITATION TITRATION

## Precipitation Reaction:

- Reactions occurring in solution may produce substances that are insoluble in the solution and thus eventually settle to the bottom or "precipitate" out.
- Typically precipitation reactions occurs in aqueous solutions between ions (i.e., the reactants are electrolytes). Often only one pair of ions actually reacts or precipitates while the other pair remains in the solution unchanged.

## Precipitation Titrations

A reaction in which the analyte and titrant form an insoluble precipitate also can form the basis for a titration. We call this type of titration a precipitation titration.

The meaning of ANALYTE is a chemical substance that is the subject of chemical analysis.
The meaning of TITRANT is a substance (such as a reagent solution of precisely known concentration) that is added in titration.

## Precipitation= Reaction that results in the formation of an insoluble product (precipitate)

Precipitate = insoluble solid that separates from solution
Metathesis/ double-displacement reaction
= reaction that involves the exchange of parts
 between two compounds

## Example: Precipitation of Lead Iodide

$\mathrm{Pbl}_{2}$

## PRECIPITATION TITRATION

## Precipitation Reactions

A precipitation reaction occurs when two or more soluble species combine to form an insoluble product that we call a precipitate. The most common precipitation reaction is a metathesis reaction, in which two soluble ionic compounds exchange parts. When a solution of lead nitrate is added to $\vec{a}$ solution of potassium chloride, for example, a precipitate of lead chloride forms. We usually write the balanced reaction as a net ionic equation, in which only the precipitate and those ions involved in the reaction are included.

## Precipitation Reactions

Precipitation is the formation of a solid in a solution
solid formed is called the precipitate
A precipitation reaction occurs when water solutions of two different ionic compounds are mixed and an insoluble solid separates out of the solution.

$$
\mathrm{KCl}+\mathrm{AgNO}_{3} \longleftrightarrow \mathrm{AgCl}+\mathrm{KNO}_{3}
$$

| Cl - solution | Precipitating | White |
| :---: | :---: | :---: |
| agent | precipitate |  |

The precipitate is itself ionic; the cation comes from one solution and the anion from another.

- Solubility product (Ksp):
- The solubility product constant, Ksp, is the equilibrium constant for a solid substance dissolving in an aqueous solution. It represents the level at which a solute dissolves in solution. The more soluble a substance is, the higher the Ksp value it has.
- When a compound is referred to as insoluble, its not completely insoluble but is slightly soluble. When substances have a limited solubility and their solubility is exceeded, the ions of the dissolved portions exist in equilibrium with a solid material. So-called "insoluble" compounds generally exhibit this property.
- The precipitate will have a definite solubility (i.e., a definite amount that will dissolve) in $\mathrm{g} / \mathrm{dm}^{-3}$ or $\mathrm{mol} / \mathrm{dm}^{-3}$ at a given temperature (a saturated solution). A small amount of un-dissolved compound usually exists in equilibrium in the aqueous phase (e.g., on the order of $0.1 \%$ ) and its concentration is constant. It is difficult to measure the un-dissociated molecule, and we are interested in the ionized form, presence of any un-dissociated species can generally be neglected.

$$
\mathrm{AgCl} \longrightarrow \mathrm{Ag}^{+}+\mathrm{Cl}^{-}
$$

$$
\mathrm{Keq}=\frac{\{\text { Prouct }\}}{\{\text { Reactant }\}}
$$

$$
\mathrm{Keq}=\frac{\left\{\mathrm{Ag}^{+}\right\}\left\{\mathrm{Cl}^{-}\right\}}{\{\mathrm{AgCl}\}}
$$

Since the concentration of a solid is a constant value that does not depend on temperature, pressure, or the presence of the solution in contact with it and can be neglected, , we simplify the above equation to.

$$
\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]=\mathrm{Keq}[\mathrm{AgCl}]=\text { constant }
$$

- This constant called constant of solubility product:

$$
\mathrm{Ksp}=\mathrm{Keq}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]
$$

Every substance that is poorly soluble in water has its own solubility product
Salt that has a lower Ksp value is the one that precipitates first, that is, if it has a low Ksp value, it indicates that the solubility of the salt is low.

## Complexometric Titrations

## Complexometry

A volumetric titration involves the formation of a soluble complex between a metal ion (as acceptor) and ligand (as donor) to form coordination bonds.
The metal ion is known as a Central metal atom.
The anion or neutral molecule is known as Ligand (L)
Metal ions are Lewis acid, accepting electron pairs from electrodonating ligands that are Lewis bases.

| $\mathrm{Ag}^{+}+$ | $: \mathrm{C}-\equiv \mathrm{N}:$ |
| :--- | :--- |
| Lewis acid | Lewis base |
| (electron pair acceptor) | (electron pair donor) |

[:N三C-Ag-C $=N:]^{-}$ complex ion

## The formation of Complexes

Complexation reactions are important in many areas of science. Complexes play an essential role in many chemical and biochemical processes. For example, the hemoglobin molecule in blood holds the iron atom tightly because the nitrogen of the hemoglobin forms strong complexing bonds, that is nitrogen is a good complexer.
Complexation reactions are widely used in analytical chemistry. One of the first uses of these reactions was for titrating cations.

Complex ions (coordination compounds) are produce from reaction of many metal ions (electrons accepter) with electron pair donors.

The donor species (or called ligands) must have at least one pair of unshared electrons for bond formation.

- Metals ions, especially transition metals, act as Lewis acids, because they accept electrons from Lewis bases
-     - When metal cations combine with Lewis bases, the resulting species is called a complex ion or coordination complexes
- COMPLEX $=$ LIGAND + METAL ION

- A ligand is an ion or molecule that forms a covalent bond with a cation or neutral metal atom by donating a pair of electrons, which are then shared by the two. Ligands can be classified into inorganic ligands such as water, ammonia, and halide ions, and organic ligands such as 8-hydroxyquinoline.
- a) anionic ligands : like $, \mathrm{SCN}^{-}, \mathrm{CN}^{-}, \mathrm{OH}^{-}, \ldots . . . . . e c t$.
-b) molecular ligands : like, $\mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{RNH}_{2}, \ldots .$. ect.
- $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right],\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{+2},\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{+2}$
- Species formed as a result of coordination can be classified as positive
- or neutral or negative :
- $\mathrm{Cu}^{+2}+4 \mathrm{NH}^{3+} \rightarrow\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{+2}$...................... cationic complex
- $\mathrm{Cu}^{+2}+\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{COO}^{-} \rightarrow \mathrm{Cu}\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{COO}\right)_{2}$..... neuteral complex
- $\mathrm{Cu}^{+2}+4 \mathrm{Cl}^{-} \rightarrow \mathrm{CuCl}_{4}^{-2}$ anionic complex

## - Coordination Number:-

- The number of covalent bonds that a cation tends to form with electron donors is called the coordination number.
- Common coordination numbers are 2, 4 and 6

- Chelates: are produced when a metal ion coordinates with two or more donor groups of a single ligand to form a five or six-member heterocyclic ring and form a cyclic structure.
- The key difference between ligands and chelates is that ligands are the chemical species that are donating or sharing their electrons with a central atom through coordination bonds, whereas chelates are compounds containing a central atom bonded with surrounding ligands.

## - A ligand that has:

- single donor group is called unidentate
- two donor groups is called bidentate
- three donor groups is called tridentate
- four donor groups is called tetradentate
- five donor groups is called pentadentate
- six donor groups is called hexadentate
- Tetradentate and hexadentate ligands are more satisfactory as titrants than ligands with a lesser number of donor groups because their reactions with cations are more
- A titration based on the formation of a coordination complex is known as a complexometric titration.
- Complexometric titrations are particularly useful for the determination of a mixture of different metal ions in solution.

## - Chelation

- Chelate : It is a complex formed between the ligand containing two or more donor groups and metal to form ring structure. (heterocyclic rings or chelate rings).
- Chelating agents: organic molecules containing two or more donor groups which combine with metal to form complex having ring structure.
Chelates are usually insoluble in water but soluble in organic solvent.

Glycine

$\mathrm{Cu}^{2+}$ complex with glycine.

The following reaction between the metal ion $\mathrm{Cd}^{2 *}$ and the ligand $\mathrm{NH}_{3}$ is typical of a complexation reaction.

$$
\begin{equation*}
\mathrm{Cd}^{2^{2}}(\mathrm{aq})+4: \mathrm{NH}_{3}(\mathrm{aq}) \rightleftharpoons \mathrm{Cd}\left(\mathrm{NH}_{3}\right)_{4}^{2^{+}}(\mathrm{aq}) \tag{6.4.35}
\end{equation*}
$$

The product of this reaction is a metal-ligand complex. In writing this reaction we show ammonia as : $\mathrm{NH}_{3}$, using a pair of dots to emphasize the pair of electrons it donates to $\mathrm{Cd}^{2+}$. In subsequent reactions we will omit this notation.

## Metal-Ligand Formation Constants

We characterize the formation of a metal-ligand complex by a formation constant, $K_{f}$. The complexation reaction between $\mathrm{Cd}^{2+}$ and $\mathrm{NH}_{3}$, for example, has the following equilibrium constant.

$$
\begin{equation*}
K_{\mathrm{f}}=\frac{\left[\mathrm{Cd}\left(\mathrm{NH}_{3}\right)_{4}^{2+}\right]}{\left[\mathrm{Cd}^{2+}\right]\left[\mathrm{NH}_{3}\right]^{4}}=5.5 \times 10^{7} \tag{6.4.36}
\end{equation*}
$$

The reverse of reaction 6.4 .35 is a dissociation reaction, which we characterize by a dissociation constant, $\boldsymbol{K}_{\mathrm{d}}$, that is the reciprocal of $\boldsymbol{K}_{\mathrm{f}}$.

Many complexation reactions occur in a stepwise fashion. For example, the reaction between $\mathrm{Cd}^{2+}$ and $\mathrm{NH}_{3}$ involves four successive reactions.

$$
\begin{array}{ll}
\mathrm{Cd}^{2+}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightleftharpoons \mathrm{Cd}\left(\mathrm{NH}_{3}\right)^{2+}(\mathrm{aq})_{2} & (6.4 .37) \\
\mathrm{Cd}\left(\mathrm{NH}_{3}\right)^{2+}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightleftharpoons \mathrm{Cd}\left(\mathrm{NH}_{3}\right)_{2}^{2+}(\mathrm{aq}) & (6.4 .38) \\
\mathrm{Cd}\left(\mathrm{NH}_{3}\right)_{2}^{2+}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightleftharpoons \mathrm{Cd}\left(\mathrm{NH}_{3}\right)_{3}{ }^{2+}(\mathrm{aq}) & (6.4 .39) \\
\mathrm{Cd}\left(\mathrm{NH}_{3}\right)_{3}^{2+}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightleftharpoons \mathrm{Cd}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(\mathrm{aq}) & (6.4 .40)
\end{array}
$$

To avoid ambiguity, we divide formation constants into two categories. Stepwise formation constants, which we designate as $K_{i}$ for the ith step, describe the successive addition of one ligand to the metalligand complex from the previous step. Thus, the equilibrium constants for reactions $6.4 .37-6.4 .40$ are, respectively, $K_{1}, K_{2}, K_{3}$, and $K_{4}$. Overall, or cumulative formation constants, which we designate as $\beta_{i}$, describe the addition of $i$ ligands to the free metal ion. The equilibrium constant in equation 6.4.36 is correctly identified as $\beta_{4}$, where

$$
\beta_{4}=K_{1} \times K_{2} \times K_{3} \times K_{4}
$$

In general

$$
\mathbf{B}_{\mathbf{i}}=\mathbf{K}_{1} \times \mathbf{K}_{2} \times \ldots \times \mathbf{K}_{\mathbf{i}}
$$

$$
(6.4 .42)
$$

Stepwise and overall formation constants for selected metal-ligand complexes are in Appendix 12.

## Metal-Ligand Complexation and Solubility

A formation constant characterizes the addition of one or more ligands to a free metal ion. To find the equilibrium constant for a complexation reaction involving a solid, we combine appropriate $K_{s p}$ and $K_{f}$ expressions. For example, the solubility of AgCl increases in the presence of excess chloride as the result of the following complexation reaction.

$$
A g C 1(s)+\mathrm{Cl}^{-}(\mathrm{aq}) \rightleftharpoons A g \mathrm{Ag}_{2}^{-}(\mathrm{aq}) \quad(6.4 .43)
$$

We can write this reaction as the sum of three other reactions with known equilibrium constants-the solubility of AgCl , described by its $K_{\text {sp }}$

$$
\begin{equation*}
\mathrm{AgCl}(\mathrm{~s}) \rightleftharpoons \mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}) \tag{6.4.44}
\end{equation*}
$$

and the stepwise formation of $\mathrm{AgCl}_{2}^{-}$, described by $K_{1}$ and $K_{2}$.

$$
\begin{equation*}
\mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}) \rightleftharpoons \mathrm{AgCl}(\mathrm{aq}) \tag{6.4.45}
\end{equation*}
$$

$\mathrm{AgCl}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}) \rightleftharpoons \mathrm{AgCl}_{2}^{-}(\mathrm{aq})$
(6.4.46)

The equilibrium constant for reaction 6.4.43, therefore, is $K_{\mathrm{sp}} \times K_{1} \times K_{2}$.

## Examiniple 6.4

Determine the value of the equilibrium constant for the reaction

$$
\begin{equation*}
\mathbf{P b C l}_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{PbCl}_{2}(\mathrm{aq}) \tag{6.4.47}
\end{equation*}
$$

## Solution

We can write this reaction as the sum of three other reactions. The first of these reactions is the solubility of $\mathrm{PbCl}_{2}(s)$, described by its $K_{\text {sp }}$ reaction.

$$
\mathrm{PbCl}_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Pb}^{2+}(\mathrm{aq})+2 \mathrm{Cl}^{-}(\mathrm{aq})
$$

The remaining two reactions are the stepwise formation of $\mathrm{PbCl}_{2}(a q)$, described by $K_{1}$ and $K_{2}$.

$$
\begin{aligned}
& \mathrm{Pb}^{2+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}) \rightleftharpoons \mathrm{PbCl}^{+}(\mathrm{aq}) \\
& \mathrm{PbCl}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}) \rightleftharpoons \mathrm{PbCl}_{2}(\mathrm{aq})
\end{aligned}
$$

Using values for $K_{\mathrm{sp}}, K_{1}$, and $K_{2}$ from Appendix 10 and Appendix 12, we find that the equilibrium constant is

$$
\begin{equation*}
\mathrm{K}=\mathrm{K}_{\mathrm{sp}} \times \mathrm{K}_{1} \times \mathrm{K}_{2}=\left(1.7 \times 10^{-5}\right) \times 38.9 \times 1.62=1.1 \times 10^{-3} \tag{6.4.51}
\end{equation*}
$$

## Practicice Exercise 6.3

What is the equilibrium constant for the following reaction? You will find appropriate equilibrium constants in Appendix 10 andAppendix 11 .

$$
\begin{equation*}
A g B r(s)+2 S_{2} O_{3}^{2-}(\mathrm{aq}) \rightleftharpoons A g\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}(\mathrm{aq})+\mathrm{Br}^{-}(\mathrm{aq}) \tag{6.4.52}
\end{equation*}
$$

We can write the reaction as a sum of three other reactions. The first reaction is the solubility of $\operatorname{AgBr}(s)$, which we characterize by its $K_{\text {spp }}$.

$$
A g B r(s) \rightleftharpoons A g^{+}(\mathrm{aq})+\mathrm{Br}^{-}(\mathrm{aq})
$$

The remaining two reactions are the stepwise formation of $\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}^{3-}$, which we characterize by $K_{1}$ and $K_{2}$.

$$
\begin{gathered}
\mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{S}_{2} \mathrm{O}_{3}^{2-}(\mathrm{aq}) \rightleftharpoons \mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)^{-}(\mathrm{aq}) \\
\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)^{-}(\mathrm{aq})+\mathrm{S}_{2} \mathrm{O}_{3}^{2-}(\mathrm{aq}) \rightleftharpoons \mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}(\mathrm{aq})
\end{gathered}
$$

Using values for $K_{\text {sp }}, K_{1}$, and $K_{2}$ from Appendix 10 and Appendix 11, we find that the equilibrium constant for our reaction is

$$
\mathbf{K}=\mathbf{K}_{\text {sp }} \times \mathbf{K}_{1} \times \mathbf{K}_{2}=\left(5.0 \times 10^{-13}\right)\left(6.6 \times 10^{8}\right)\left(7.1 \times 10^{4}\right)=23
$$

## Composition of EDTA solution as a function of pH :

The most common echelon (or titrant) used in complexation titration is EDTA (ethylenediaminetetraacetic acid).
EDTA is a weak acid dissociate in four steps :

$$
\begin{aligned}
& \mathrm{H}_{4} \mathrm{Y}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{H}_{3} \mathrm{Y}^{-}+\mathrm{H}_{3} \mathrm{O}^{+} \\
& \mathrm{H}_{3} \mathrm{Y}^{-}+\mathrm{H}_{3} \mathrm{O}^{+} \longrightarrow \mathrm{H}_{2} \mathrm{y}^{-2}+\mathrm{H}_{3} \mathrm{O}^{+} \\
& \mathrm{H}_{2} \mathrm{y}^{-2} \mathrm{H}_{3} \mathrm{O}^{+} \mathrm{Hy}^{-3}+\mathrm{H}_{3} \mathrm{O}^{+} \\
& \mathrm{Hy}^{-3}+\mathrm{H}_{3} \mathrm{O}^{+} \longrightarrow \mathrm{y}^{-4}+\mathrm{H}_{3} \mathrm{O}^{+}
\end{aligned}
$$

These values refer to that the first two protons are lost much more readily than the remaining two.
$\mathrm{CT}=\left[\mathrm{H}_{4} \mathrm{y}\right]+\left[\mathrm{H}_{3} \mathrm{y}-\right]+\left[\mathrm{H}_{2} \mathrm{y}^{-2}\right]+\left[\mathrm{Hy}^{-3}\right]+\left[\mathrm{y}^{-4}\right]$
It found that EDTA values depend upon the pH of the solution, which is :

- a) when $\mathrm{pH}(3-6), \mathrm{H}_{2} \mathrm{y}^{-2}$ is predominant.
-b) when $\mathrm{pH}(6-10), \mathrm{Hy}^{-3}$ is predominant.
- c) at $\mathrm{pH}>10, \mathrm{y}^{-4}$ is predominant.
- EDTA is hexadentate because each nitrogen atom has an unshared pair of electrons in addition to four acidic hydrogens, thus, the molecule has six potential sites for bonding with a metal ion.
- the presence of hydrophilic groups such as $\mathrm{COOH}, \mathrm{SO}_{3} \mathrm{H}, \mathrm{NH}_{2}$, and OH , when both acidic and basic groups are present, the complex will be soluble over a wide pH range.
- When hydrophilic groups are absent, the solubilities of both the chelating agent and the metal chelate will be low, but they will be soluble in organic solvents
- Plotting precipitation titration curves
-     - Consider the titration of $\mathrm{Cl}^{-}$with a standard solution of $\mathrm{AgNO}_{3}$.
- Titration curve prepared by plotting $\mathrm{pCl}\left(-\log \left[\mathrm{Cl}^{-}\right]\right)$against the volume of $\mathrm{AgNO}_{3}$ in a manner similar to acid-base titration.
- Before titration started - only have $\mathrm{Cl}^{-}$.

$$
\mathrm{pCl}=-\log \left[\mathrm{Cl}^{-}\right]
$$

- Titration proceed - part of $\mathrm{Cl}^{-}$is removed from solution by precipitation as AgCl .

$$
\mathrm{pCl}=-\log \text { [remaining Cl-] }
$$

-     - At equivalence point - we have solution a saturated solution of AgCl [ $\mathrm{Cl}-]=\sqrt{K S P}$
-     - Excess $\mathrm{AgNO}_{3}$ added - excess $\mathrm{Ag}^{+}$. [Cl-] is determine from the concentration of $\mathrm{Ag}^{+}$and Ksp.

$$
\text { - }\left[\mathrm{Cl}^{-}\right]=\mathrm{Ksp} /\left[\mathrm{Ag}^{+}\right]
$$

- Plots of titration curves are normally sigmoidal curves consisting of pAg (or pAnalyte) versus volume of $\mathrm{AgNO}_{3}$ solution added.
- A useful relationship can be derived by taking the negative logarithm of both sides of a solubility-product expression. Thus, for silver chloride,

$$
\begin{gathered}
\cdot \mathrm{Ksp}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right] \\
\cdot \log K s p=-\log \left(\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]\right) \\
\cdot-\log K s p=-\log \left[\mathrm{Ag}^{+}\right]+\left(-\log \left[\mathrm{Cl}^{-}\right]\right) \\
\cdot p K s p=p \mathrm{Ag}^{+}+p \mathrm{Cl}^{-}
\end{gathered}
$$

- Notes :
- 1) In precipitation titration we are using molar and formal conc. and we are not using normal conc.
- 2) Precipitation titration methods are used to determine halogen ions.
-3) Precipitation titration curves are plotted as:
-4) Precipitation titration curve is influenced by the concentrations. of $\mathrm{Ag}^{+}$ and $\mathrm{Cl}^{-}$
-5) Precipitation titration curve is influenced by KSP value (completeness of reaction). when the KSP value is small the titration curve is perfect.
- Ansewer of example :
- a) before adding AgNO :
- $\mathrm{NaCl} \rightarrow \mathrm{Na}^{+}+\mathrm{Cl}^{-}$
$0.1 \quad 0.1 \quad 0.1$
- $\mathrm{pCl}=-\log \left[\mathrm{Cl}^{-}\right]=-\log 0.1=1$
- pAg = zero
-b) after adding 10 mL of $\mathrm{AgNO}_{3}$ :
$\mathrm{NaCl}+\mathrm{AgNO}_{3} \rightarrow \mathrm{AgCl}+\mathrm{NaNO}_{3}$
(50x0.1) (10x0.1) 0
$\begin{array}{lll}5 & 1 & 0\end{array}$
$\begin{array}{lll}4 & 0 & 1\end{array}$
- $\left[\mathrm{Cl}^{-}\right]=\frac{4}{60}=6.7 \times 10^{-2}$
- $\mathrm{pCl}=-\log 6.7 \times 10^{-2}=1.17$
- $\left[\mathrm{Ag}^{+}\right]=\frac{K S P}{\left[\mathrm{Cl}^{-}\right]}=\frac{1.82 \times 10^{-10}}{6.7 \times 10^{-2}}=2.7 \times 10^{-9}$
- $\mathrm{pAg}=-\log 2.7 \times 10^{-9}=8.57$
-c) when adding 49.95 ml of $\mathrm{AgNO}_{3}$ :
$-\mathrm{NaCl}+\mathrm{AgNO}_{3} \rightarrow \quad \mathrm{AgCl}+\mathrm{NaNO}_{3}$ (50x0.1) (49.95x0.1) 0

5
0.05
4.95

0

0
0.05

- $[\mathrm{Cl}-]=\frac{0.05}{99.95}=5 \times 10^{-5}$
- $\mathrm{pCl}=-\log 5 \times 10^{-5}=4.3$
- $\left[\mathrm{Ag}^{+}\right]=\frac{K S P}{\left[\mathrm{Cl}^{-}\right]}=\frac{1.82 \times 10^{-10}}{5 \times 10^{-10}}=0.36 \times 10^{-5} \quad \mathrm{pAg}=-\log 0.36 \times 10^{-5}, \mathrm{pAg}=5.44$
-d) at equivalent point, when adding 50 ml of $\mathrm{AgNO}_{3}$ :
- $\mathrm{NaCl}+\mathrm{AgNO}_{3} \rightarrow \mathrm{AgCl}+\mathrm{NaNO}_{3}$

| $(50 \times 0.1)$ | $(50 \times 0.1)$ | 0 |
| :---: | :---: | :---: |
| 5 | 5 | 0 |
| 0 | 0 | 5 |

- $\left[\mathrm{Ag}^{+}\right]=\left[\mathrm{Cl}^{-}\right]=1.82 \times 10^{-10}$
- $[\mathrm{Cl}-]^{2}=1.82 \times 10^{-10}$
- $\left[\mathrm{Ag}^{+}\right]=\left[\mathrm{Cl}^{-}\right]=1.35 \times 10^{-5}$
- $\mathrm{pCl}=\mathrm{pAg}=4.87$
- e) after adding 52.5 ml of AgNO :
- $\mathrm{NaCl}+\mathrm{AgNO}_{3} \rightarrow \mathrm{AgCl}+\mathrm{NaNO}_{3}$
(50x0.1) $\quad(52.5 \times 0.1) \quad 0$

| 5 | 5.25 | 0 |
| :---: | :---: | :---: |
| 0 | 0.25 | 0.25 |

- $\left[\mathrm{Ag}^{+}\right]=\frac{0.25}{102.5}=2.4 \times 10^{-3}$
- $\left[\mathrm{Cl}^{-}\right]=\frac{1.82 \times 10^{-10}}{2.4 \times 10^{-3}}=$
- $\mathrm{pAg}=2.62$
- $\mathrm{pCl}=7.12$

## Factors affecting the solubility of precipitates

- Solubility is important factor in gravimetric analysis which requires pure material. This means there is a need for washing the precipitate to remove impurities and obtain pure precipitate .
1 - Nature of the precipitate: If the attraction between solvent molecules and solute ions is higher than that between solute ions in the crystal then the salt is soluble.
2 - Nature of solvent: Two properties of the solvent affecting the solubility of the solute, these are polarity and dielectric value. Solvent of more polarity means more attraction between solute ions and solvent molecules. The attraction at crystal surface decreases with higher electric constant of the solvent. Water as with high polarity and dielectric constant value is a good solvent for nearly all inorganicionic salts .Organic solvents such as chloroform, alcohols are good solvents for organic salts (non polar compounds).
- 3 - Temperature : Higher temperature means higher solubility ; in water this solubility process in endothermic.
- 4 - Common ion effect: The ion that forms the precipitate is the common ion if the solvent contain these common ions. The solubility of the salts decreases compared with pure solvents. Other uncommon ions increases the solubility.
$5-\mathrm{pH}$ value :The concentration of hydrogen ion and hydroxide ions affect the acidity of the solution and hence the solubility of sparingly soluble solute.
- Ex.1. If the solubility of $\mathrm{AgBr}=2 \times 10^{-5} \mathrm{~g} / 100 \mathrm{ml}$ at $20^{\circ} \mathrm{C}$, calculate Ksp value? (M.Wt=187.8 g/mole)
- The solubility should be calculated in unit of mole/liter
- Concentration volume
- $2 \times 10^{-5} \quad 100 \mathrm{ml}$
- $x \quad 1000 \mathrm{ml}$
$\mathrm{X}=\frac{2 \times 10^{-5} \times 1000}{100}=2 \times 10^{-4} \mathrm{~g} / \mathrm{L}$
Concentration mole/L= (solute weight (g)/L) / F. Wt
Or: Concentration mole/L= (solute weight (g)/L) / M.Wt
$\mathrm{X}=\frac{2 \times 10^{-4}}{187.8}=1.065 \times 10^{-6} \mathrm{~mol} / \mathrm{L}$
- This means that $1.065 \times 10^{-6}$ mole of AgBr is dissolved in one liter of solution (available as ions). Therefore each liter of the solution contains:
- $\left[\mathrm{Ag}^{+}\right]=1.065 \times 10^{-6} \mathrm{~mole} / \mathrm{L}$
- $\left[\mathrm{Br} \mathrm{B}^{-}\right]=1.065 \times 10^{-6} \mathrm{~mole} / \mathrm{L} \quad 2 \times 10^{-5}$
- Or: $M=$ mole/L
- $\mathrm{M}=\frac{W t}{M \cdot W t} \times \frac{1000}{V m L}=\quad \Rightarrow \mathrm{M}=\frac{2 \times 10^{-5}}{187.8} \times \frac{1000}{100}$
- = $1.065 \times 10^{-6} \mathrm{~mole} / \mathrm{L}$
- Ksp can be calculated as follows:

- $\mathrm{Ksp}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Br} \mathrm{r}^{-}\right]=1.065 \times 10^{-6} \mathrm{~mole} / \mathrm{L} \times 1.065 \times 10^{-6} \mathrm{~mole} / \mathrm{L}$
$\cdot=1.134 \times 10^{-12}$

# ANALYTICAL CHEMISTRY 

## LECTURE- 5 <br> BY

## Dr. ABBAS HASAN FARIS

## Oxidation-Reduction <br> Reactions

- An oxidation-reduction reaction is any chemical reaction in which the oxidation number of a molecule, atom, or ion changes by gaining or losing an electron. Redox reactions are common and vital to some of the basic functions of life, including photosynthesis, respiration, combustion, and corrosion or rusting.
- Often called "redox" reactions
-     - Electrons are transferred between the reactants
- One substance is oxidized, loses electrons
- Reducing agent
- Another substance is reduced, and gains electrons
- Oxidizing agent
- Oxidation numbers change during the reaction

### 4.4 Oxidation-Reduction / Redox Reactions

## Electron donor

Electron acceptor
$\mathrm{Zn}(s)+\mathrm{CuSO}_{4}(a q) \longrightarrow \mathrm{ZnSO}_{4}(a q)+\mathrm{Cu}(s)$ $\mathrm{Zn} \longrightarrow \mathrm{Zn}^{2+}+2 \mathrm{e}^{-} \mathrm{Zn}$ is oxidized Zn is the reducing agent $\mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu} \mathrm{Cu}{ }^{2+}$ is reduced $\mathrm{Cu}^{2+}$ is the oxidizing agent

Copper wire reacts with silver nitrate to form silver metal. What is the oxidizing agent in the reaction?
$\mathrm{Cu}(s)+2 \mathrm{AgNO}_{3}(a q) \longrightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(a q)+2 \mathrm{Ag}(s)$ $\mathrm{Cu} \longrightarrow \mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \mathrm{Cu}$ is oxidized Cu is the reducing agent $\mathrm{Ag}^{+}+1 \mathrm{e}^{-} \longrightarrow \mathrm{Ag} \quad \mathrm{Ag}^{+}$is reduced $\quad \mathrm{Ag}^{+}$is the oxidizing agent

Chemical Equations are simple.

$4 \mathrm{Fe}+3 \mathrm{O}_{2}$

### 6.4.4 Oxidation-Reduction (Redox) Reactions

An oxidation-reduction reaction occurs when electrons move from one reactant to another reactant. As a result of this electron transfer, these reactants undergo a change in oxidation state. Those reactants that experience an increase in oxidation state undergo oxidation, and those experiencing a decrease in oxidation state undergo reduction. For example, in the following redox reaction between $\mathrm{Fe}^{3+}$ and oxalic acid, $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$, iron is reduced because its oxidation state changes from +3 to +2 .

$$
2 \mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons 2 \mathrm{Fe}^{2+}(\mathrm{aq})+2 \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

Oxalic acid, on the other hand, undergoes oxidation because the oxidation state for carbon increases from +3 in $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ to +4 in $\mathrm{CO}_{2}$.

We can divide a redox reaction, such as reaction 6.4.53, into separate half-reactions that show the oxidation and the reduction processes.

$$
\begin{align*}
& \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons 2 \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+2 \mathrm{e}-  \tag{6.4.54}\\
& \mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{e}-\rightleftharpoons \mathrm{Fe}^{2+}(\mathrm{aq}) \tag{6.4.55}
\end{align*}
$$

- Example
- $\mathrm{Zn}(\mathrm{s})+\mathrm{CuSO}_{4}(\mathrm{aq}) \rightarrow \mathrm{ZnSO}_{4}(\mathrm{aq})+\mathrm{Cu}(\mathrm{s})$
- $\mathrm{Zn}(\mathrm{s})+\mathrm{Cu}^{2+}(\mathrm{aq}) \rightarrow \mathrm{Zn}^{2+}(\mathrm{aq})+\mathrm{Cu}(\mathrm{s})$
- Zinc is losing 2 electrons and oxidized.
- Reducing agent
- $\mathrm{Zn}(\mathrm{s}) \rightarrow \mathrm{Zn}^{2+}(\mathrm{aq})+2 \mathrm{e}-$
- Copper ions are gaining the 2 electrons.
- Oxidizing agent
- $\mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{e}-\rightarrow \mathrm{Cu}(\mathrm{s})$
- Rules for assigning oxidation numbers
-1. Elements (uncombined) are 0.
- Al, N2, He, Zn, Ag, Br2, O2, O3
- 2. Oxidation numbers must sum to the overall charge of the species.
- $\left(\mathrm{SO}_{4}\right)^{2-}=-2$ ( O is usually -2 so....)
- ? $+4(-2)=-2$
- Solve: ? - $8=-2$ ? $=+6$ (S)
- Balancing redox reactions
-     - Electrons (charge) must be balanced as well as number and types of atoms - Consider this net ionic reaction:

$$
\text { - } \mathrm{Al}(\mathrm{~s})+\mathrm{Ni}^{2+}(\mathrm{aq}) \rightarrow \mathrm{Al}^{3+}(\mathrm{aq})+\mathrm{Ni}(\mathrm{~s})
$$

-     - The reaction appears balanced as far as the number and type of atoms are concerned, but look closely at the charge on each side.

$$
\cdot \mathrm{Al}(\mathrm{~s})+\mathrm{Ni}^{2+}(\mathrm{aq}) \rightarrow \mathrm{Al}^{3+}(\mathrm{aq})+\mathrm{Ni}(\mathrm{~s})
$$

-     - Divide reaction into two half-reactions

$$
\begin{aligned}
& \cdot \mathrm{Al}(\mathrm{~s}) \rightarrow \mathrm{Al}^{3+}(\mathrm{aq})+3 \mathrm{e}- \\
& \cdot \mathrm{Ni}^{2+}(\mathrm{aq})+2 \mathrm{e}-\rightarrow \mathrm{Ni}(\mathrm{~s})
\end{aligned}
$$

-     - Multiply by a common factor to equalize electrons (the number of electrons lost must equal number of electrons gained)

$$
\begin{aligned}
& \cdot 2\left[\mathrm{Al}(\mathrm{~s}) \rightarrow \mathrm{Al}^{3+}(\mathrm{aq})+3 \mathrm{e}-\right] \\
& \cdot 3\left[\mathrm{Ni}^{2+}(\mathrm{aq})+2 \mathrm{e}-\rightarrow \mathrm{Ni}(\mathrm{~s})\right]
\end{aligned}
$$

- Cancel electrons and write balanced net ionic reaction
- $2 \mathrm{Al}(\mathrm{s}) \rightarrow 2 \mathrm{Al}^{3+}(\mathrm{aq})+6 \mathrm{e}-$
- $3 \mathrm{Ni}^{2+}(\mathrm{aq})+6 \mathrm{e}-\rightarrow 3 \mathrm{Ni}(\mathrm{s})$
- $2 \mathrm{Al}(\mathrm{s})+3 \mathrm{Ni}^{2+}(\mathrm{aq}) \rightarrow 2 \mathrm{Al}^{3+}(\mathrm{aq})+3 \mathrm{Ni}(\mathrm{s})$

## - Reagent EDTA

- Disodium salt of EDTA is a water-soluble chelating agent and is always preferred. It is non-hygroscopic and a very stable sequestering agent.
- EDTA has the broadest general application because:

1. It has a low price
2. The unique structure, which has six ligands atoms
3. It forms strainless five-membered rings

- The selectivity of EDTA can be increased by the following procedures: Masking and demasking agent
-     - Masking agents: Protects some components of the analyte from reacting with EDTA. These reagents form complexes with interfering ions which are more stable than complexes formed with EDTA.
- Masking agents: A reagent added to prevent reaction of some metal ion with EDTA (block metal ions)
-     - Examples of masking agent: (give examples of masking agent)
- KCN: It is used as masking agent for $\mathrm{Ag}+, \mathrm{Cu}^{2+}, \mathrm{Cd}^{2+}, \mathrm{Co}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Zn}^{2+}, \ldots$ etc.

$$
\begin{array}{lc}
\cdot \mathrm{M}^{+}+2 \mathrm{CN}^{-} & {\left[\mathrm{M}(\mathrm{CN})_{2}\right]^{-}} \\
-\mathrm{M}^{+}+4 \mathrm{CN}^{-}
\end{array} \quad[\mathrm{M}(\mathrm{CN}) 4]^{2-} .
$$

- Triethanolamine: It is used as masking agent for $\mathrm{Fe}^{3+}, \mathrm{Al}^{3+}$ and $\mathrm{Sn} 2+$
- Fluoride (e.g. $\mathrm{NH}_{4} \mathrm{~F}$ ): It is used as masking agent for $\mathrm{Fe}^{3+}$ and $\mathrm{Al}^{3+}$ to give $\left[\mathrm{FeF}_{6}\right]^{3-}$ and $\left[\mathrm{AlF}_{6}\right]^{3-}$
- Iodide (KI): It is used as masking agent for $\mathrm{Hg}^{2+}$ to give tetraiodo complex $\left(\mathrm{Hgl}_{4}\right)$
-     - Demasking agent: Releasing masking agent from the analyte.
- Reagents that release of a metal ion from a masking agent
- Example:
- Example of using masking and demasking agents in complexometry is the analysis of 3 metals, $\mathrm{Cu}, \mathrm{Cd}$, and Ca . The following method of analysis is followed
- Step 1: All metals are titrated
- Ca
- Cd + EDTA

Ca-EDTA

- Cu

Cd-EDTA

- How can we determine a mixture of metals using complexometric titration?
- Step 2: Only Ca titrated
- [Cu, Cd] + cyanide ion $\qquad$ $\longrightarrow$
[Cu-cyanide]complex] EDTA [Cd-cyanide]complex] EDTA
- $\mathrm{Ca}+$ cyanide $\longrightarrow$ ion no reaction EDTA Ca-EDTA
-     - Step 3: Cd and Ca are titrated
$\cdot[\mathrm{Cd}-\mathrm{cyanide}]$ complex $+\mathrm{HCHO} \longleftrightarrow \mathrm{Cd}^{2+}$ (free)
- demasking agent
- [Cu-cyanide]complex + HCHO no reaction
- Cd

Cd-EDTA

+ EDTA
- Cu

Cu-EDTA

- Oxidation with $\mathrm{H}_{2} \mathrm{O}_{2}$ releases $\mathrm{Cu}^{2+}$ from [Cu ${ }^{+}$-Thiourea] complex.

## Titration curves

- For derivation of the titration curve, consider the titration of 50.0 mL of 0.1 M solution of $\mathrm{Mg}^{2+}$ (buffered at pH 10 ) with 0.1 M EDTA solution.

We calculate the concentration of $\mathrm{Mg}^{2+}$ (as $\mathrm{pMg}=-\log (\mathrm{Mg})$ and plotted versus the volume added from ETDA

1) pMg before the addition of EDTA
$\mathrm{Mg}^{2+}=0.1 \mathrm{M}$, s. $\mathrm{o}, \mathrm{pMg}=-\log (0.1)=1.0$
At start of Titration when no titrant EDTA is added to the solution, only $\mathrm{Mg}^{2+}$, will be present in the solution. The concentration of $\mathrm{Mg}^{2+}$ can be given as,

- 2) pMg after adding 10.0 mL EDTA, we will calculate the remaining unchelated Mg solution in the whole solution ( 60 ml )
- $\mathrm{Mg}^{+2}+\mathrm{y}^{-4} \longrightarrow \mathrm{Mgy}^{-2}$
- $50 \times 0.1 \quad 10 \times 0.1 \quad 0$
- 5110
- $40 \quad 4$
- $M_{M g}{ }^{+}{ }^{2}$ unreacted $=\frac{(50 \times 0.1)-(10 \times 0.1)}{50+10}=0.067 \mathrm{M}$
- $\mathrm{P}_{\mathrm{Mg}}=-\log (0.067)=1.17$

3) pMg after adding 25.0 mL EDTA, we will calculate the remaining unchelated Mg solution in the whole solution ( 75 ml )
$\boldsymbol{M}_{M g+2}$ unreacted $=\frac{(50 \times 0.1)(25 \times 0.1)}{50+25}=0.033 \mathrm{M}$
$P_{M g}=-\log (0.033)=1.48$

- 4) pMg at the equivalence point
- At this Point, 50 mL of EDTA have been added to completely react with Mg solution
- We will use the stability constant to calculate the pMg
- $\mathrm{Mg}^{+2}+\mathrm{y}^{-4} \longleftrightarrow \quad \mathrm{MgY}^{-2}$

| $\mathbf{5 0} \times \mathbf{0 . 1}$ | $\mathbf{5 0} \times \mathbf{0 . 1}$ | 0 |
| :---: | :---: | :--- |
| 5 | 5 | 0 |
| 0 | 0 | $5-\mathrm{a}$ |

- $K_{\text {stab }}=\frac{\left(M g Y^{-2}\right)}{\left(M g^{2+}\right)\left(Y^{-4}\right)}=\mathbf{5} \times \mathbf{1 0 8}$
- Concentration of $\mathrm{MgY}^{2-}$ is calculated as follows
- $\boldsymbol{M}_{\boldsymbol{M g}}{ }^{+}{ }^{2}=\frac{\mathbf{5 0 \times 0 . 1}}{\mathbf{5 0 + 5 0}}=0.05 \mathrm{M}$
- $\mathrm{M}_{\mathrm{MgY}^{-2}}{ }^{-2} \frac{\mathbf{5 0 \times 0 . 1}}{\mathbf{5 0}+\mathbf{5 0}}=0.05-\mathrm{a}$
- Substitute at equation $\mathrm{K}_{\text {stab }}=\frac{(0.05-\mathrm{a})}{\boldsymbol{a}^{2}}=\mathbf{5} \times \mathbf{1 0 8}$
$\cdot \mathrm{a}$, is neglected because it is very small relative to 0.05
- So, $\frac{(0.05-a)}{a^{2}} \quad \mathrm{a}=\left(\mathrm{Mg}^{+2}\right)=1.0 \times 10^{-5}, \mathrm{P}_{\mathrm{Mg}}=5.0$

5) pMg , beyond the equivalence point:

By adding $\mathbf{6 0} \mathbf{~ m L}$ of the 0.1 M EDTA
$\mathrm{M}_{\mathrm{MgY}-2}=\frac{\mathbf{5 0 * 0 . 1}}{\mathbf{5 0}+\mathbf{6 0}}-\mathrm{a}$
Neglect the term a
and then substitute ( $\mathrm{MgY}^{2-}$ ) of $5 / 110 \mathrm{M}$ in $\mathrm{K}_{\text {stab }}$ equation

- There will be an excess from EDTA
- $\mathrm{Y}^{-4}=\frac{(\mathbf{6 0} \times \mathbf{0 . 1 ) ( 5 0 \times 0 . 1 )}}{\mathbf{5 0}+\mathbf{6 0}}=1 / 110$
$\cdot \frac{5 / 110}{(1 / 110) \times(a)}=5.0 \times 108$
$\cdot \mathrm{a}=1 \times 10^{8} \mathrm{M} \quad$ And $\mathrm{pMg}=8.0$
The titration curve is plotted by using the previous data Volume added (ml )EDTA pMg

## Oxidation-Reduction/ Redox Reactions

(electron transfer reactions)
Example: formation of MgO from Mg and $\mathrm{O}_{2}$

| Oxidation reaction: <br> half-reaction involves lose e | Reduction reaction: <br> half-reaction involves gain e |
| :---: | :---: |
| $2 \mathrm{Mg} \longrightarrow 2 \mathrm{Mg}^{2+}+4 \mathrm{e}^{-}$ | $\mathrm{O}_{2}+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{O}^{2-}$ |

Half reaction: Reaction that shows e- involved in redox reaction

## Thermodynamics of Redox Reactions

Unlike precipitation reactions, acid-base reactions, and complexation reactions, we rarely express the equilibrium position of a redox reaction using an equilibrium constant. Because a redox reaction involves a transfer of electrons from a reducing agent to an oxidizing agent, it is convenient to consider the reaction's thermodynamics in terms of the electron.

For a reaction in which one mole of a reactant undergoes oxidation or reduction, the net transfer of charge, $Q$, in coulombs is

$$
Q=n F
$$

where $n$ is the moles of electrons per mole of reactant, and $F$ is Faraday's constant ( $96,485 \mathrm{C} / \mathrm{mol}$ ). The free energy, $\Delta G$, to move this charge, $Q$, over a change in potential, $E$, is

$$
\Delta G=\mathrm{EQ}
$$

The change in free energy (in $\mathrm{kJ} / \mathrm{mole}$ ) for a redox reaction, therefore, is

$$
\Delta G=-n F E
$$

The electrical potential is a measure of the relative energy of an electron on a molecule/atom.

- When $\Delta G^{0}<0$, energy is released and reactions proceed without added energy. When $\Delta \mathrm{G}^{0}>0$, energy is required to make a reaction proceed. It is possible for $\mathrm{NO}_{2}$ - to oxidize $\mathrm{H}_{2} \mathrm{O}$ to $\mathrm{O}_{2}$, but this would require additional energy. Reduction potential values can be used to calculate $\Delta \mathrm{G}^{0}$ according to the Nernst Equation:

$$
\Delta G^{Y}=-\eta A^{Q}
$$

- $\mathrm{n}=$ number of e - transferred
- F = Faraday constant ( $23 \mathrm{kcal} \mathrm{V}^{-1} \mathrm{~mol}^{-1}$ )
- $\Delta E^{0}=E^{0}$ (oxidizing agent) - $E^{0}$ (reducing agent) $=E^{0}$ (reduction) $-E^{0}$ (oxidation)
- $\Delta \mathrm{E}^{0}$ and $\Delta \mathrm{G}^{0}$ have opposite signs, so when $\Delta \mathrm{E}^{0}>0$, then $\Delta \mathrm{G}^{0}$ will be negative
- Since a redox reaction is spontaneous, the amount of energy released must be greater than the amount of energy absorbed. Thus, all redox reactions are exothermic in nature.
- A spontaneous redox reaction is characterized by a negative value of $\Delta \mathrm{G}^{\circ}$, which corresponds to a positive value of $\mathrm{E}^{\circ}$ cell.

## Equilibrium Constant and Free Energy Change for an Electrochemical Cell

- Two important parameters that can be determined from a cell potential are the equilibrium constant for the cell reaction and the free energy change for the cell reaction.
- 1- Determining the Equilibrium Constant from $\mathrm{E}^{\circ}{ }_{\text {cell }}$
- 2- Determining the Standard State Free Energy Change from $\mathrm{E}^{\circ}{ }_{\text {cell }}$
- 3- Determining the Non-Standard Free Energy Change
- To calculate the equilibrium constant for an electrochemical cell we need to know:
- the standard state potential for a cell
- the half-reactions involved
- The Nernst equation is used in calculating the equilibrium constant.

| cathode: | $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(\mathrm{aq})+14 \mathrm{H}^{+}(\mathrm{aq})+6 \mathrm{e}^{-} \rightarrow 2 \mathrm{Cr}^{3+}(\mathrm{aq})+7 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | $E_{\text {cathode }}^{\circ}=1.36 \mathrm{~V}$ |
| :--- | :--- | :--- |
| anode: | $6 \mathrm{Br}^{-}(\mathrm{aq}) \rightarrow 3 \mathrm{Br}_{2}(\mathrm{aq})+6 \mathrm{e}^{-}$ | $E_{\text {anode }}^{\circ}=1.09 \mathrm{~V}$ |
| overall: | $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(\mathrm{aq})+6 \mathrm{Br}^{-}(\mathrm{aq})+14 \mathrm{H}^{+}(\mathrm{aq}) \rightarrow 2 \mathrm{Cr}^{3+}(\mathrm{aq})+3 \mathrm{Br}_{2}(\mathrm{aq})+7 \mathrm{H}_{2} 0(\mathrm{l})$ | $E_{\text {cell }}^{\circ}=0.27 \mathrm{~V}$ |

## B

We can now calculate $\Delta G^{0}$ using Equation 20.5.7. Because six electrons are transferred in the overall reaction, the value of $n$ is 6 :

$$
\begin{aligned}
\Delta G^{\circ} & =-(n)(F)\left(E_{\text {cell }}^{\circ}\right) \\
& =-(6 \mathrm{~mole})[96,485 \mathrm{~J} /(\mathrm{V} \cdot \mathrm{~mol})(0.27 \mathrm{~V})] \\
& =-15.6 \times 10^{4} \mathrm{~J} \\
& =-156 \mathrm{~kJ} / \mathrm{mol} \mathrm{Cr}
\end{aligned} \mathrm{C}_{7}^{2-} .
$$

- The free energy change of any reaction is given by the following

$$
\begin{aligned}
& \Delta G=\Delta F^{0}+R T \ln \frac{\text { [products ] }}{[\text { reactants }]} \\
& -n F \Delta E=-n F \Delta E^{o}+R T \ln \frac{\text { [products ] }}{[\text { reactants }]} \\
& \Delta E=\Delta E^{o}-\frac{R T}{n F} \ln \frac{\text { [products ] }}{[\text { reactants] }}
\end{aligned}
$$

When Ecell $=+$ the reaction proceeds spontaneously to the right. As the reaction proceeds the E+cell becomes smaller and smaller until eventually it reaches zero. An Ecell= 0 means that there is no net reaction occurring and that the cell has reached equilibrium. When Ecell $=0$ The Q term in the Nernst equal equals to $\mathrm{K}(\mathrm{Q}=\mathrm{K})$

```
E= EO}-\operatorname{log}\textrm{K}\quad\mathrm{ Where K = equilibrium constant
and
Eo= = 0.0592
```

- The Nernst equation allows the reduction potential to be calculated at any temperature and concentration of reactants and products; the standard reaction potential must be measured at 298 K and with each solution at 1 M .
- The Nernst equation is:
- $\mathrm{E}_{\text {cell }}^{0}=\frac{R T}{n F} \ln \boldsymbol{Q}$
- E : is the reduction potential for the specified non-standard state
- $\mathrm{E}_{0}$ : is the standard reduction potential
- R: and F are the gas and Faraday constants, respectively
- N : is the number of electrons transferred in the reaction
- If $T$ is held constant at 298 K , the Nernst equation can be condensed using the values for the constants $R$ and $F$ :
- 

At equilibrium $Q=K$. Substituting in $K$ for $Q$, and the values for $R, T$, and $F$, we get:

- $\mathrm{E}_{\text {cell }}^{0}=\frac{0.0257}{n} \ln Q=\mathrm{E}^{0}{ }_{\text {cell }}=\frac{0.0592}{n} \log K$
- $\Delta G=\Delta G^{0}+R T \ln Q$
- $-\mathrm{nFE}_{\text {cell }}=-\mathrm{nF} \mathrm{E}_{\text {cell }}^{\circ}+R T \ln Q$
- It can be further simplified if the reaction has reached equilibrium, as in that case $Q$ is the equilibrium constant $K$ :
- This equation allows the equilibrium constant to be calculated just from the standard reduction potential and the number of electrons transferred in the reaction
- $\operatorname{InK}=\frac{n E_{0}}{0.0257}$
- $\log K=\frac{n E_{0}}{0.0592}$

## Standard Potentials

A redox reaction's standard potential, $E^{\circ}$, provides an alternative way of expressing its equilibrium constant and, therefore, its equilibrium position. Because a reaction at equilibrium has a $\Delta G$ of zero, the potential, $E$, also must be zero at equilibrium. Substituting these values into equation 6.4 .61 and rearranging provides a relationship between $E^{\circ}$ and $K$.

$$
\begin{equation*}
E^{\circ}=\frac{0.05916}{n} \log K \tag{6.4.62}
\end{equation*}
$$

## INote

A standard potential is the potential when all species are in their standard states. You may recall that we define standard state conditions as: all gases have partial pressures of 1 atm , all solutes have concentrations of 1 mol/L, and all solids and liquids are pure.

We generally do not tabulate standard potentials for redox reactions. Instead, we calculate $E^{\circ}$ using the standard potentials for the corresponding oxidation half-reaction and reduction half-reaction. By convention, standard potentials are provided for reduction half-reactions. The standard potential for a redox reaction, $E^{\circ}$, is

$$
E^{\circ}=E^{\circ} \text { red } E_{o x}^{o} \quad(6.4 .63)
$$

where $E^{\circ}$ red and $E^{\circ}$ ox are the standard reduction potentials for the reduction half-reaction and the oxidation half-reaction.

$$
\mathbf{E}_{\text {Box/Bred }}=\mathbf{E}_{\text {Aox/Ared }}
$$

This is an important observation because we can use either half-reaction to monitor the titration's progress.

Before the equivalence point the titration mixture consists of appreciable quantities of the titrand's oxidized and reduced forms. The concentration of unreacted titrant, however, is very small. The potential, therefore, is easier to calculate if we use the Nernst equation for the titrand's half-reaction

$$
E_{\mathrm{rxn}}=E_{A_{\mathrm{OXX}} / A_{\mathrm{redl}}}^{o}-\frac{R T}{n F} \ln \frac{\left[A_{\mathrm{red}}\right]}{\left[A_{\mathrm{ox}}\right]}
$$

Note : Although the Nernst equation is written in terms of the half-reaction's standard state potential, a matrix-dependent formal potentialoften is used in its place. See Appendix 13 for the standard state potentials and formal potentials for selected half-reactions.

After the equivalence point it is easier to calculate the potential using the Nernst equation for the titrant's half-reaction.

$$
\boldsymbol{E}_{\mathrm{rxn}}=\boldsymbol{E}_{B_{\mathrm{ox}}^{o} / B_{\mathrm{red}}}^{o}-\frac{R T}{n F} \ln \frac{\left[B_{\mathrm{red}}\right]}{\left[B_{\mathrm{oxx}}\right]}
$$

Because we cannot measure the potential for a single half-reaction, we arbitrarily assign a standard reduction potential of zero to a reference half-reaction and report all other reduction potentials relative to this reference. The reference half-reaction is

$$
\begin{equation*}
2 \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+2 \mathrm{e}-\rightleftharpoons 2 \mathrm{H}_{2} \mathrm{O}(1)+\mathrm{H}_{2}(\mathrm{~g}) \tag{6.4.64}
\end{equation*}
$$

Appendix 13 contains a list of selected standard reduction potentials. The more positive the standard reduction potential, the more favorable the reduction reaction under standard state conditions. Thus, under standard state conditions the reduction of $\mathrm{Cu}^{2+}$ to $\mathrm{Cu}\left(E^{\mathrm{o}}=+0.3419 \mathrm{~V}\right)$ is more favorable than the reduction of $\mathrm{Zn}^{2+}$ to $\mathrm{Zn}\left(E^{\mathrm{o}}=-0.7618 \mathrm{~V}\right)$.

## Example 6.5

Calculate (a) the standard potential, (b) the equilibrium constant, and (c) the potential when $\left[\mathrm{Ag}^{+}\right]=0.020 \mathrm{M}$ and $\left[\mathrm{Cd}^{2+}\right]=0.050 \mathrm{M}$, for the following reaction at $25^{\circ} \mathrm{C}$.

$$
\begin{equation*}
\mathrm{Cd}(\mathrm{~s})+2 \mathrm{Ag}^{+}(\mathrm{aq}) \rightleftharpoons 2 \mathrm{Ag}(\mathrm{~s})+\mathrm{Cd}^{2+}(\mathrm{aq}) \tag{6.4.65}
\end{equation*}
$$

## Solution

(a) In this reaction Cd is undergoing oxidation and $\mathrm{Ag}^{+}$is undergoing reduction. The standard cell potential, therefore, is

$$
\mathrm{E}^{\circ}=\mathrm{E}^{\circ}{ }_{\mathrm{Ag}+/ \mathrm{Ag}}-\mathrm{E}^{\circ} \mathrm{Cd}^{2+} / \mathrm{Cd}=0.7996-(-0.4030)=1.2026 \mathrm{~V}
$$

(b) To calculate the equilibrium constant we substitute appropriate values into equation 6.4.62.

$$
\begin{equation*}
E^{0}=1.2026 \mathrm{~V}=\frac{0.05916 \mathrm{~V}}{2} \log K \tag{6.4.67}
\end{equation*}
$$

Solving for $K$ gives the equilibrium constant as

$$
\begin{aligned}
& \log K=40.6558 \\
& K=4.527 \times 10^{40}
\end{aligned}
$$

(c) To calculate the potential when $\left[\mathrm{Ag}^{+}\right]$is 0.020 M and $\left[\mathrm{Cd}^{2+}\right]$ is 0.050 $M$, we use the appropriate relationship for the reaction quotient, $Q$, in equation 6.4.61.

$$
\begin{gather*}
E=E^{\circ}-\frac{0.05916 \mathrm{~V}}{n} \log \frac{\left[\mathrm{Cd}^{2+}\right]}{\left[\mathrm{Ag}^{+}\right]^{2}}  \tag{6.4.70}\\
E=1.2606 \mathrm{~V}-\frac{0.05916 \mathrm{~V}}{2} \log \frac{(0.050)}{(0.020)^{2}} \tag{6.4.71}
\end{gather*}
$$

$$
\begin{equation*}
\mathrm{E}=1.14 \mathrm{~V} \tag{6.4.72}
\end{equation*}
$$

## Pranctice Exercisse 6.4

For the following reaction at $25^{\circ} \mathrm{C}$
$5 \mathrm{Fe}^{2+}(\mathrm{aq})+\mathrm{MnO}_{4}^{-}(\mathrm{aq})+8 \mathrm{H}^{+}(\mathrm{aq}) \rightleftharpoons 5 \mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{Mn}^{2+}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}(1)$
calculate (a) the standard potential, (b) the equilibrium constant, and (c) the potential under these conditions: $\left[\mathrm{Fe}^{2+}\right]=0.50 \mathrm{M},\left[\mathrm{Fe}^{3+}\right]=0.10 \mathrm{M}$, $\left[\mathrm{MnO}_{4}{ }^{-}\right]=0.025 \mathrm{M},\left[\mathrm{Mn}^{2+}\right]=0.015 \mathrm{M}$, and a pH of 7.00 . See Appendix 13 for standard state reduction potentials.

The two half-reactions are the oxidation of $\mathrm{Fe}^{2+}$ and the reduction of $\mathrm{MnO}_{4}{ }^{-}$.

$$
\begin{gathered}
\mathrm{Fe}^{2+}(\mathrm{aq}) \rightleftharpoons \mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{e}- \\
\mathrm{MnO}_{4}^{-}(\mathrm{aq})+8 \mathrm{H}^{+}(\mathrm{aq})+5 \mathrm{e}^{-} \rightleftharpoons \mathrm{Mn}^{2+}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{gathered}
$$

From Appendix 13, the standard state reduction potentials for these halfreactions are

$$
\mathrm{E}^{\circ}{ }_{\mathrm{Fe} 3+/ \mathrm{Fe} 2+}=0.771 \mathrm{~V} \quad \mathrm{E}^{\circ} \mathrm{MnO} 4-/ \mathrm{Mn} 2+=1.51 \mathrm{~V}
$$

(a) The standard state potential for the reaction is

$$
\mathrm{E}^{\circ}=\mathrm{E}^{\circ} \mathrm{MnO}_{4}^{-} / \mathrm{Mn}^{2+}-\mathrm{E}^{\circ} \mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}=1.51 \mathrm{~V}-0.771 \mathrm{~V}=0.74 \mathrm{~V}
$$

(b) To calculate the equilibrium constant we substitute appropriate values into equation 6.4.62.

$$
\mathbb{E}^{\infty}=0.74 V=\frac{0.05916}{5} \log F
$$

Solving for $K$ gives its value as

$$
\log K=62.5 \quad K=3.2 \times 10^{62}
$$

(c) To calculate the potential under these non-standard state conditions, we make appropriate substitutions into the Nernst equation.

$$
\begin{gathered}
\boldsymbol{E}=\boldsymbol{E}^{\circ}-\frac{R T}{n F^{2}} \ln \frac{\left[\mathrm{Mn}^{2+}\right]\left[\mathrm{Fe}^{3+}\right]^{5}}{\left[\mathrm{MnO}_{4}^{-}\right]\left[\mathrm{Fe}^{2+}\right]^{5}\left[\mathrm{H}^{+}\right]^{8}} \\
\boldsymbol{E}=0.74-\frac{0.05916}{5} \log \frac{(0.015)(0.10)^{5}}{(0.025)(0.50)^{5}\left(1 \times 10^{-7}\right)^{8}} \\
\boldsymbol{E}=0.74-\frac{0.05916}{5} \log \frac{(0.015)(0.10)^{5}}{(0.025)(0.50)^{5}\left(1 \times 10^{-7}\right)^{8}}=0.12 \mathrm{~V}
\end{gathered}
$$

## Note

When writing precipitation, acid-base, and metal-ligand complexation reaction, we represent acidity as $\mathrm{H}_{3} \mathrm{O}^{+}$. Redox reactions are more commonly written using $\mathrm{H}^{+}$instead of $\mathrm{H}_{3} \mathrm{O}^{+}$. For the reaction in Practice Exercise 6.4, we could replace $\mathrm{H}^{+}$with $\mathrm{H}_{3} \mathrm{O}^{+}$and increase the stoichiometric coefficient for $\mathrm{H}_{2} \mathrm{O}$ from 4 to 12, e.g.,

$$
\begin{equation*}
5 \mathrm{Fe}^{2+}(\mathrm{aq})+\mathrm{MnO}_{4}^{-}(\mathrm{aq})+8 \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq}) \rightleftharpoons 5 \mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{Mn}^{2+}(\mathrm{aq})+12 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \tag{6.4.74}
\end{equation*}
$$

- Example:
- Calculate the equilibrium constant for the redox reaction at $25^{\circ} \mathrm{C}$,

$$
\mathrm{Sr}(\mathrm{~s})+\mathrm{Mg}^{+2}(\mathrm{aq}) \rightleftarrows \mathrm{Mg}(\mathrm{~s})+\mathrm{Sr}^{+2}
$$

- that occurs in the Galvanic cell.

$$
\mathrm{E}^{\mathrm{O}}{ }_{\mathrm{Mg}+2 / \mathrm{Mg}}=-2.37 \mathrm{~V} \text { and } \mathrm{E}_{\mathrm{Sr}+2 / \mathrm{sr}}^{\mathrm{O}}=-2.89 \mathrm{~V}
$$

Hint: As per the electrochemical series of the elements, the metals that are placed below in the series are reduced by accepting electrons in the presence of the elements that are placed higher in the electrochemical series. We shall calculate the value of $\mathrm{E}_{\text {cell }}^{0}$ from the potential of cathode and anode given and use the formula given to find the equilibrium constant.

$$
\text { Formula Used: } \mathrm{E}_{\text {cell }}^{0}=\mathrm{E}^{0}{ }_{\text {reduction }}-\mathrm{E}_{\text {oxidation }}^{0}
$$

## - Complete Step By Step Solution

- Given that,
- $\mathrm{Sr}(\mathrm{s})+\mathrm{Mg}^{2+}(\mathrm{aq}) \rightleftarrows \mathrm{Mg}(\mathrm{s})+\mathrm{Sr}^{2+}(\mathrm{aq})$,
- as per this reaction, strontium is oxidized in the presence of magnesium to form strontium dispositive ions in the solution and the magnesium metal are discharged at the cathode. The equilibrium constant for the above reaction is as follows:
- $\mathrm{Kc}=\frac{\left[\mathrm{Sr}{ }^{+2}\right][\mathrm{Mg}]}{[\mathrm{Sr}]\left[\mathrm{Mg}{ }^{+2}\right]}$
- Now, this equilibrium constant is related to the cell potential by the Nernst Equation which is as follows:

$$
\cdot \mathrm{E}_{\text {cell }}^{0}=\frac{0.059}{n} \log K
$$

- where, $\mathrm{E}^{0}{ }_{\text {cell }}$ is the cell potential and n is the number of electrons transferred in the process. Since strontium gives up two electrons in the process to get oxidized hence $\mathrm{n}=2$.
- $\mathbf{E}_{\text {cell }}^{0}=\mathrm{E}_{\text {reduction }}^{0}-\mathrm{E}_{\text {oxidation }}^{0}$
- As strontium is getting oxidized and magnesium is getting reduced, so the $\mathrm{E}^{0}{ }_{\text {cell }}$ is,
- $\mathrm{E}^{0}$ cell $=\mathrm{E}_{\text {reduction }}^{0}-\mathrm{E}^{0}{ }_{\text {oxidation }}$
- $E_{\text {cell }}^{0}=-2.37-(-2.89)=0.52 \mathrm{~V}$
- Now, $\Delta G^{0}=-R T \operatorname{InK}$ eq
- Or, $-\Delta n$ FE $^{0}=-$ RTInK ${ }_{\text {eq }}$
- Therefore, $\mathrm{InK}_{\text {eq }}=\frac{-\mathrm{nF} \Delta \mathrm{E}^{0}}{R T}=\frac{2 \times 96500 \times 0.52}{8.314 \times 298}=40.507$
- Therefore, $\operatorname{lnK}_{\text {eq }}=40.507$,
- Or K $_{\text {eq }}=3.908 \times 10^{17}$

## Calculating the Titration Curve

Let's calculate the titration curve for the titration of 50.0 mL of 0.100 M $\mathrm{Fe}^{2+}$ with $0.100 \mathrm{MCe}^{4+}$ in a matrix of $1 \mathrm{M} \mathrm{HClO}_{4}$. The reaction in this case is

$$
\mathrm{Fe}^{2+}(\mathrm{aq})+\mathrm{Ce}^{4+}(\mathrm{aq}) \rightleftharpoons \mathrm{Ce}^{3+}(\mathrm{aq})+\mathrm{Fe}^{3+}(\mathrm{aq}) \quad 9.1
$$

## Note

In $1 \mathrm{M} \mathrm{HClO}_{4}$, the formal potential for the reduction of $\mathrm{Fe}^{3+}$ to $\mathrm{Fe}^{2+}$ is +0.767 V , and the formal potential for the reduction of $\mathrm{Ce}^{4+}$ to $\mathrm{Ce}^{3+i s}+1.70 \mathrm{~V}$.

Because the equilibrium constant for reaction 9.1 is very large-it is approximately $6 \times 10^{15}$-we may assume that the analyte and titrant react completely.

## Note

Step 1: Calculate the volume of titrant needed to reach the equivalence point
The first task is to calculate the volume of Ce ${ }^{4+}$ needed to reach the titration's equivalence point. From the reaction's stoichiometry we know that
moles $\mathrm{Fe}^{2+}=$ moles $\mathrm{Ce}^{4+}$

$$
\mathrm{M}_{E e} \times \mathrm{K}_{\mathrm{Ee}}=\mathrm{M}_{\mathrm{Ce}} \times \mathrm{K}_{\mathrm{Ce}}
$$

Solving for the vollume of $\mathrm{Ce}^{4+}$ gives the equivalence point volume as

$$
V_{\mathrm{eq}}=V_{\mathrm{Ce}}=\frac{M_{\mathrm{Fe}} V_{\mathrm{Fe}}}{M_{\mathrm{Ce}}}=\frac{(0.100 \mathrm{M})(50.0 \mathrm{~mL})}{(0.100 \mathrm{M})}=50.0 \mathrm{~mL}
$$

## Note

Step 2: Calculate the potential before the equivalence point by determining the concentrations of the titrand's oxidized and reduced forms, and using the Nernst equation for the titrand's reduction half-reaction.

Before the equivalence point, the concentration of unreacted $F e^{2+}$ and the concentration of $\mathrm{Fe}^{3+}$ are easy to calculate. For this reason we find the potential using the Nernst equation for the $F e^{3+/ F} e^{2+}$ half-reaction.

$$
E=E_{\mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}}^{o}-\frac{R T}{n F} \log \frac{\left[\mathrm{Fe}^{2+}\right]}{\left[\mathrm{Fe}^{3+}\right]}=+0.767 \mathrm{~V}-0.05916 \log \frac{\left[\mathrm{Fe}^{2+}\right]}{\left[\mathrm{Fe}^{3+}\right]}
$$

For example, the concentrations of $\mathrm{Fe}^{2+}$ and $\mathrm{Fe}^{3+}$ after adding 10.0 mL of titrant are

$$
\begin{gathered}
{\left[\mathrm{Fe}^{2+}\right]=\frac{\text { initial moles } \mathrm{Fe}^{2+}-\text { moles } \mathrm{Ce}}{} \begin{array}{c}
\text { total volume } \\
= \\
=\frac{(0.100 \mathrm{M})(50.0 \mathrm{~mL})-(0.100 \mathrm{M})(10.0 \mathrm{~mL})}{50.0 \mathrm{~mL}+10.0 \mathrm{~mL}}=\frac{M_{\mathrm{Fe}} V_{\mathrm{Fe}}-M_{\mathrm{Ce}} V_{\mathrm{Ce}}}{V_{\mathrm{Fe}}+V_{\mathrm{Ce}}} \\
{\left[\mathrm{Fe}^{3+}\right]=\frac{\text { moles Ced }}{}+67 \times 10^{-2} \mathrm{M}} \\
\text { total volumed }
\end{array}=\frac{M_{\mathrm{Ce}} V_{\mathrm{Ce}}}{V_{\mathrm{Fe}}+V_{\mathrm{Ce}}}} \\
=\frac{(0.100 \mathrm{M})(10.0 \mathrm{~mL})}{50.0 \mathrm{~mL}+10.0 \mathrm{~mL}}=1.67 \times 10^{-2} \mathrm{M}
\end{gathered}
$$

Substituting these concentrations into equation 9.2 gives a potential of

$$
E=+0.767 \mathrm{~V}-0.05916 \log \frac{6.67 \times 10^{-2} \mathrm{M}}{1.67 \times 10^{-2} \mathrm{M}}=+0.731 \mathrm{~V}
$$

## Note

Step 3: Calculate the potential after the equivalence point by determining the concentrations of the titrant's oxidized and reduced forms, and using the Nernst equation for the titrant's reduction half-reaction.

After the equivalence point, the concentration of $\mathrm{Ce}^{3+}$ and the concentration of excess $\mathrm{Ce}^{4+}$ are easy to calculate. For this reason we find the potential using the Nernst equation for the $\mathrm{Ce}^{4+} / \mathrm{Ce}^{3+}$ half-reaction.

$$
\boldsymbol{E}=\boldsymbol{E}_{\mathrm{Ce}^{4+} / \mathrm{Ce}^{3+}}^{o}-\frac{R T}{n \boldsymbol{F}} \log \frac{\left[\mathrm{Ce}^{3+}\right]}{\left[\mathrm{Ce}^{4+}\right]}=+1.70 \mathrm{~V}-0.05916 \log \frac{\left[\mathrm{Ce}^{3+}\right]}{\left[\mathrm{Ce}^{4+}\right]}
$$

For example, after adding 60.0 mL of titrant, the concentrations of $\mathrm{Ce}^{3+}$ and $\mathrm{Ce}^{4+}$ are

$$
\begin{aligned}
{\left[\mathrm{Ce}^{3+}\right] } & =\frac{\text { initial moles Fe }{ }^{2+}}{\text { total volume }}=\frac{M_{\mathrm{Fe}} V_{\mathrm{Fe}}}{V_{\mathrm{Fe}}+V_{\mathrm{Ge}}} \\
& =\frac{(0.100 \mathrm{M})(50.0 \mathrm{~mL})}{50.0 \mathrm{~mL}+160.0 \mathrm{~mL}}=4.55 \times 10^{-3} \mathrm{MI}
\end{aligned}
$$

$$
\begin{aligned}
{\left[\mathrm{Ce}^{4+}\right] } & =\frac{\text { moles Ce } \mathrm{e}^{4+} \text { added }- \text { initial moles Fe }{ }^{2+}}{\text { total volumae }}=\frac{M_{\mathrm{Ce}} V_{\mathrm{Ce}}-M_{\mathrm{Fe}} V_{\mathrm{Fe}}}{V_{\mathrm{Fe}}+V_{\mathrm{Ce}}} \\
& =\frac{(0.100 \mathrm{M})(60.0 \mathrm{~mL})-(0.100 \mathrm{M})(50.0 \mathrm{~mL})}{50.0 \mathrm{~mL}+60.0 \mathrm{~L} \mathrm{~L}}=9.09 \times 10^{-3} \mathrm{M}
\end{aligned}
$$

Substituting these concentrations into equation 9.3 gives a potential of

$$
E=+1.70 \mathrm{~V}-0.05916 \log \frac{4.55 \times 10^{-2} \mathrm{M}}{9.09 \times 10^{-3} \mathrm{MI}}=+1.66 \mathrm{~V}
$$

## Note

Step 4: Calculate the potential at the equivalence point.
At the titration's equivalence point, the potential, Eeq, in equation 9.2 and equation 9.3 are identical. Adding the equations together to gives

Because $\left[\mathrm{Fe}^{2+}\right]=\left[C \mathrm{e}^{4+}\right]$ and $\left[C \mathrm{e}^{3+}\right]=\left[\mathrm{Fe}^{3+}\right]$ at the equivalence point, the log term has a value of zero and the equivalence point's potential is

$$
\begin{equation*}
E=E_{\mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}}^{o}-\frac{R T}{n F} \log \frac{\left[\mathrm{Fe}^{2+}\right]}{\left[\mathrm{Fe}^{3+}\right]}=+0.767 \mathrm{~V}-0.05916 \log \frac{\left[\mathrm{Fe}^{2+}\right]}{\left[\mathrm{Fe}^{3+}\right]} \tag{9.16}
\end{equation*}
$$

$$
\begin{equation*}
E=E_{\mathrm{Ce}^{4+}}^{o} / \mathrm{Ce}^{3+}-\frac{R T}{n F} \log \frac{\left[\mathrm{Ce}^{3+}\right]}{\left[\mathrm{Ce}^{4+}\right\rceil}=+1.70 \mathrm{~V}-0.05916 \log \frac{\left[\mathrm{Ce}^{3+}\right]}{\left[\mathrm{Ce}^{4+}\right\rceil} \tag{9.17}
\end{equation*}
$$

$$
E_{\text {eq }}=\frac{E_{\mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}}^{o}+E_{\mathrm{Ce}^{4+} / \mathrm{Ce}^{3+}}^{o}}{2}=\frac{0.767 \mathrm{~V}+1.70 \mathrm{~V}}{2}=1.23 \mathrm{~V}
$$

Additional results for this titration curve are shown in Table 9.15 and Figure 1.囲

Table 9.15 Data for the Titration of 50.0 mL of $0.100 \mathrm{M} \mathrm{Fe}^{2+}$ with $0.100 \mathrm{M} \mathrm{Ce}^{4+}$

| Volume of $\mathbf{C e}^{4+}(\mathbf{m L})$ | $E(\mathbf{V})$ | Volume $\mathbf{C e}^{4+}(\mathbf{m L})$ | $E(\mathbf{V})$ |
| :---: | :---: | :---: | :---: |
| 10.0 | 0.731 | 60.0 | 1.66 |
| 20.0 | 0.757 | 70.0 | 1.68 |
| 30.0 | 0.777 | 80.0 | 1.69 |
| 40.0 | 0.803 | 90.0 | 1.69 |
| 50.0 | 1.23 | 100.0 | 1.70 |

Figure 1 Titration curve for the titration of 50.0 mL of $0.100 \mathrm{M} \mathrm{Fe}{ }^{2+}$ with 0.100 M Ce ${ }^{4+}$. The red points correspond to the data in Table 9.15. The blue line shows the complete titration curve.

## Practice Exercise

Calculate the titration curve for the titration of 50.0 mL of $0.0500 \mathrm{M} \mathrm{Sn}^{2+}$ with O. $100 \mathrm{M} \mathrm{Tl}^{3+}$. Both the titrand and the titrant are 1.O M in HCl. The titration reaction is

$$
\operatorname{Sn}^{2+}(\mathrm{aq})+T 1^{3+}(\mathrm{aq}) \longrightarrow \operatorname{Sn}^{4+}(\mathrm{aq})+T 1^{+}(\text {aq })
$$

## Sketching a Redox Titration Curve

To evaluate the relationship between a titration's equivalence point and its end point we need to construct only a reasonable approximation of the exact titration curve. In this section we demonstrate a simple method for sketching a

## Concept of the Instrumental Chemical Analysis

Instrumental analysis is a field of analytical chemistry that investigates analytes using scientific instruments.
Classification of Instrumental Analytical Methods:-
1- Qualitative instrumental analysis is that measured property indicates presence of analyte in matrix
2- Quantitative instrumental analysis is that magnitude of measured property is proportional to concentration of analyte in matrix

Species of interest: All constituents including analyte and Matrix-analyte (concomitants)
Often need pretreatment - chemical extraction, distillation, separation, precipitation

## - Classical:

- Qualitative - identification by color, indicators, boiling points, odors
- Quantitative - mass or volume (e.g. gravimetric, volumetric)

## - Instrumental:

- Qualitative - chromatography, electrophoresis and identification by measuring physical property (e.g. spectroscopy, electrode potential)
- Quantitative - measuring property and determining relationship to concentration (e.g. spectrophotometry, mass spectrometry) Often, same instrumental method used for qualitative and quantitative analysis.

## - Instrumental techniques

- 1- Spectroscopic methods - measuring the interaction between the analyte and electromagnetic radiation (or the production of radiation by an analyte).
- 2- Electroanalytic methods - measure an electrical property (i.e., potential, current, resistance, amperes, etc.) chemically related to the amount of analyte.

## - Features of instrumental analysis methods compared to

 classical- 1- More sensitive: they can detect very small amounts of a substance in a small amount of sample that can be up to the ppm
- 2- More selective and quality
- 3- great speed and accuracy (they reliably identify elements and compounds)
- 4- Most of the methods are non-destructive, that is used in cases that do not require destroying the sample

## Spectroscopy

- Spectroscopy is a branch of science which studies the interaction of electromagnetic radiation with matter where the interaction of radiation with chemical species is measured to obtain characteristics quality and quantity of the species.
* Spectroscopic techniques can be divided in to two
> Atomic spectroscopy (atomic absorption and atomic emission spectroscopy)
> Molecular spectroscopy (Uv-Vis, IR, NMR, MS)

Electromagnetic radiation is a form of energy that is transmitted through space at enormous velocities. Electromagnetic radiation, or light, is described by the properties of both waves and particles nature.

- We can use different terms to describe light:
- Color
- Wavelength
- Frequency
- Light is composed of electromagnetic waves that travel through some medium.
- The properties of the medium determine how light travels through it.
- In a vacuum, light waves travel at a speed of $3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$ OR 186,000 miles/s.
- The speed of light in a vacuum is a constant that is tremendously important in nature and science-it is given the symbol, C

## HIGH ENERGY

## LOW ENERGY

[^0]The Electromagnetic Spectrum
Chart by Lesp/Uniuersity of Colorado, Boulder

- An electromagnetic wave is characterized by several fundamental properties, including its frequency, velocity, amplitude, phase angle, polarization, and direction of propagation.
- Because light behaves like a wave, we can describe it in one of two ways-by its wavelength or by its frequency.
$>$ Wavelength, ${ }^{-} \lambda$ " : the linear distance between successive maxima or minima of a wave. Mostly measured in $\mathrm{nm}=10^{-9} \mathrm{~m}$
$>$ The units of wavelength are the micrometer ( $1 \mu \mathrm{~m}=10^{-6} \mathrm{~m}$ ), usually called $\Rightarrow$ micron. The unit widely used in spectroscopy is the angstrom ( $1 \mathrm{~A}=10^{-10} \mathrm{~m}$ ).
$>$ Frequancy: $(v)$ the umber of oscillations of the field that occurs per second.
$>$ Frequency $(v)$ : how many times the wave goes up and down in a period of time. $n$ has units of inverse time ( $1 / \mathrm{s}=\mathrm{Hz}$ [hertz]).

## Electromagnetic Radiation

- Speed of light can be expressed as $C=v \lambda$
- where ${ }^{-} \lambda^{\prime \prime}$ is the wavelength;
- $v$ is the frequency, and $\bar{c}$ the speed of light in a medium.
- $\mathrm{c}=$ speed of light ( $3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$ )
- $\lambda=$ wavelength ( m )
- $v=$ frequency $\left(s^{-1}\right)$
- The type of light (ultraviolet, visible, infrared, $x$-ray, etc.) is defined by either its frequency or wavelength:
- The higher the frequency, the higher the energy of radiation a photon of high frequency (short wavelength) has higher energy content than one of lower frequency (longer wavelength).

Wavenumber $\bar{v}$

$$
\# \text { of } \lambda \text { per cm }\left(\bar{v}=\frac{1}{\lambda}\right)
$$

Direction of wave motion

- wavenumber, $\mathrm{v}^{\prime \prime}$ another unit used to describe the wave properties of
- electromagnetic radiation which is the reciprocal of wavelength $-\tilde{v}=1 / \lambda$

PParticle Nature of light. When matter absorbs electromagnetic radiation it undergoes a change in energy. The interaction between matter and electromagnetic radiation is easiest to understand if we assume that radiation consists of a beam of energetic particles called photons. When a photon is absorbed by a sample it is destroyed and its energy acquired by the sample. The energy of a photon, in joules, is related to its frequency, wavelength, and wavenumber.
$>$ The energy of light can be determined either from its wavelength or frequency:
$>E=\frac{h c}{\lambda} \quad$ OR $\quad E=h v$
>Planck's constant: $\mathrm{h}=6.626 \times 10^{-34} \mathrm{~J} \mathrm{~s}$

- The electromagnetic spectrum is composed of a large range of wavelengths and frequencies (energies). It varies from the highly energetic gamma rays to the very low energy radio-waves. The entire range of radiation is commonly referred to as the electromagnetic spectrum.
- Example . The energy difference between the $3 p$ and the $3 s$ orbitals in a sodium atom is 2.107 eV . Calculate the $\boldsymbol{\lambda}$ (in nm) that would be absorbed in exciting the 3 s electron to the $3 p$ state $\left(I \mathrm{eV}=1.60 \times 10^{-19} \mathrm{~J}\right)$.
$>$ Solution: $\lambda=\frac{h c}{E}=\frac{6.626 \times 10^{-34} \mathrm{~J} . \mathrm{s} \times 3 \times 10^{8} \mathrm{~m} / \mathrm{s}}{2.107 \mathrm{eV} \times 1.60 \times 10^{-19} \mathrm{~J} / \mathrm{ev}}=590 \mathrm{~nm}$
>electron volt, unit of energy commonly used in atomic and nuclear physics, equal to the energy gained by an electron (a charged particle carrying unit electronic charge) when the electrical potential at the electron increases by one volt. The electron volt equals $1.602 \times 10^{-19}$ joule.
- Example: Violet light from a mercury lamp has a wavelength of 436 nm :
- Calculate energy of light

$$
E=\frac{h c}{\lambda}
$$

$=\frac{\left(6.626 \times 10^{-34} \mathrm{~J} \mathrm{~s}\right)\left(3.00 \times 108 \mathrm{~m} \mathrm{~s}^{-9}\right)}{436 \times 10^{9} \mathrm{~m}}=4.56 \times 10^{-19} \mathrm{~J}$
$>$ Atoms and molecules absorb and emit light in the ultraviolet (UV), visible (vis), infrared (IR), and microwave ( $\mu$ wave) regions of the electromagnetic spectrum.
>Absorption or emission of light in the UV and vis regions involves movement of electrons in the atom or molecule.
$>$ One reason UV light is so damaging is that the light has enough energy to break chemical bonds-biological and chemical systems

- $\mathrm{E}(\lambda=300 \mathrm{~nm})=399 \mathrm{~kJ} \mathrm{~mol}$
-Average bond energy $=380 \mathrm{~kJ} \mathrm{~mol}^{-1}$

## Electromagnetic radiation and its interactions with matter

- The interactions of radiation and matter are the subject of spectroscopic studies. The most interesting types of interactions in spectroscopy are absorption and emission of radiation by molecular or atomic species of interest which involve transitions between different energy levels of the chemical species.
- Electromagnetic radiation can interact with matter in a number of ways.
- If the interaction results in the transfer of energy from a beam of radiant energy to the matter, it is called "absorption" The reverse process in which a portion of the internal energy of matter converted into radiant energy is called "emission"..
- Absorption: When radiation passes through a transparent layer of a solid, liquid, or gas, certain frequencies may be selectively removed by the process of absorption. Here, electromagnetic energy is transferred to the atoms or molecules constituting the sample; as a result, these particles are promoted from a lower energy state to higher-energy states, or excited states. Note that at room temperature, most substances are in their lowest energy or ground state.
- In emission process, species in an excited state can emit photons of characteristic energies by returning to lower energy states or ground states. Part of the radiation which passes into matter, instead of being absorbed, may be scattered or reflected or may be re-emitted at the same wavelength or a different wavelength upon emerging from the sample. Radiation, which is neither absorbed nor scattered, may undergo changes in orientation or polarization as it passes through the sample.
- Emission: when an atom or molecule in an excited state returns to a lower energy state, the excess energy often is released as a photon, a process we call emission.
- Eg - Ee $=\Delta \mathrm{E}=\mathrm{h} v$ Absorption

$$
\text { Ee }-\mathrm{Eg}=\mathrm{h} v \text { emission }
$$

- The frequency and wavelength of electromagnetic radiation vary over many orders of magnitude. For convenience, we divide electromagnetic radiation into different regions. The electromagnetic spectrum-based on the type of atomic or molecular transition that gives rise to the absorption or emission of photons. The boundaries between the regions of the electromagnetic spectrum are not rigid, and overlap between spectral regions is possible.

$>$ X-ray photons excite inner-shell electrons
$>$ ultra-violet and visible-light photons excite outer-shell (valence) electrons
$>$ infrared photons are less energetic, and induce bond vibrations
$>$ Microwaves are less energetic still, and induce molecular rotation.

## Microwave region in electromagnetic spectrum

- Wave number $=1-100 \mathrm{~cm}^{-1}$
- Wavelength $=1 \mathrm{~cm}-100 \mu \mathrm{~m}$
- Frequency $=3 \times 10^{10}-3 \times 10^{12} \mathrm{~Hz}$
- Energy = $10-10^{3}$ Joules/mole

## Infrared region in electromagnetic spectrum

- Wave number $=14,286-12,800 \mathrm{~cm}-1$
- Wavelength $=\mathbf{7 0 0}-1000 \mathrm{~nm}$
- Frequency $=3 \times 10^{13} \mathrm{~Hz}$
- Energy = 1.7 eV - $1.24 \mathrm{meV}\left(1.07 \times 10^{-23}\right)$
$1 \mathrm{~J}=6.242 \times 10^{18} \mathrm{ev}$

## visibil region in electromagnetic spectrum

- Wave number $=14,286-12,800 \mathrm{~cm}^{-1}$
- Wavelength = 400-700 nm
- Frequency $=430 \mathrm{THz}-750 \mathrm{THz}$
- Energy = 3.3 eV - 1.7 eV

## Ultraviolte region in electromagnetic spectrum

- Wave number $=25,000-50,000 \mathrm{~cm}-1$
- Wavelength = 100-400 nm
- Frequency $=750 \mathrm{THz}-30 \mathrm{PHz}$
- Energy = 124 eV - 3.3 eV
