

# Fundumantal of Electronic I

## Second Class

Chapter01: Semiconductor Diodes

Lec01\_p1

**Munther N. Thiyab**

**2019-2020**

# Semiconductor Materials: Ge, Si, and GaAs

Semiconductors are a special class of elements having a conductivity between that of a good conductor and that of an insulator.

- They fall into two classes : single crystal and compound
- Single crystal : Germanium (Ge) and silicon (Si).
- Compound : gallium arsenide (GaAs),  
cadmium sulfide (CdS),  
gallium nitride (GaN),  
gallium arsenide phosphide (GaAsP)

The three semiconductors used most frequently in the construction of electronic devices are **Ge**, **Si**, and **GaAs**.

## History

- Diode , in 1939 was using Ge
- Transistor, in 1947 was using Ge
- In1954 Si was used in Transistor because Si is less temperature sensitive and abundantly available.
- High speed transistor was using GaAs in 1970 (which is 5 times faster compared to Si)
- Si, Ge and GaAs are the semiconductor of choice

# Atomic Structure

- Valence electrons: electrons in the outermost shell.
- Atoms with four valence electrons are called tetravalent.

# Atomic Structure

- Atoms with three valence electrons are called trivalent, and those with five are called pentavalent.

# Covalent Bonding

Covalent bonding of Si crystal

This bonding of atoms, strengthened by the sharing of electrons, is called **covalent bonding**

# Covalent Bonding

There is sharing of electrons, five electrons provided by As atom and three by the Ga atom.

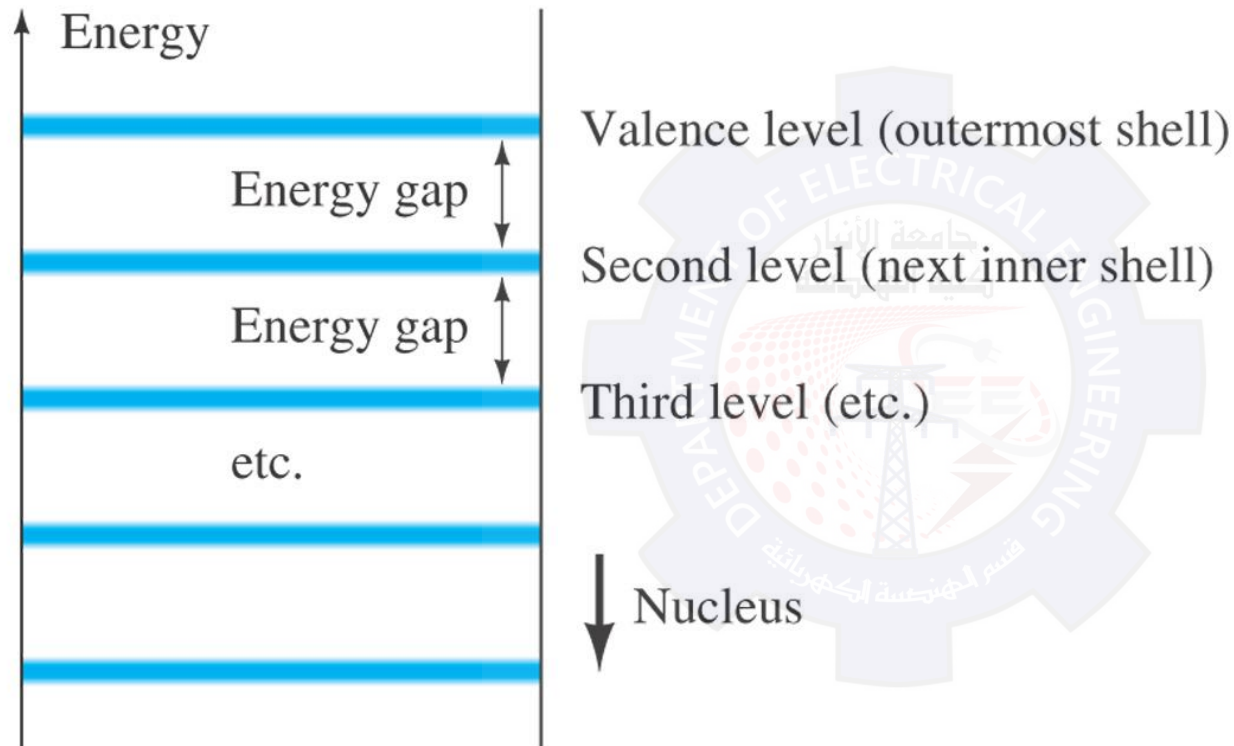

Covalent bonding of GaAs crystal

# Energy Levels

(a)

The farther an electron is from the nucleus, the higher is the energy state.

## Energy Levels

An electron in the valence band of silicon must absorb more energy than one in the valence band of germanium to become a free carrier. [free carriers are free electrons due only to external causes such as applied electric fields established by voltage sources or potential difference.

# n-Type and p-Type materials

## n-Type Material

- ❑ n-Type materials are created by adding elements with **five** valence electrons such as antimony, arsenic, and phosphorous.
- ❑ There is a fifth electron due to the (Sb) atom that is relatively free to move in the n-Type material.
- ❑ The atoms (in this case is antimony (Sb)) are called **donor atoms**.

# n-Type and p-Type materials

## n-Type Material

**The free electrons due to the added atoms have higher energy levels and require less energy to move to conduction band.**

## n-Type and p-Type materials

### p-Type Material

Boron (B)

□ p-Type materials are created by adding atoms with **three** valence electrons such as boron, gallium, and indium.

□ In this case, an insufficient number of electrons to complete the covalent bonds.

□ The resulting vacancy is called a “**hole**” represented by small circle or plus sign indicating absence of a negative charge.

□ The atoms (in this case boron(B)) are called **acceptor atoms**.

# Majority and Minority carriers

Two currents through a diode:

## Majority Carriers

- The majority carriers in n-type materials are electrons.
- The majority carriers in p-type materials are holes.

## Minority Carriers

- The minority carriers in n-type materials are holes.
- The minority carriers in p-type materials are electrons.
