

Lecture 7

5. Pressure and Its Units

A Pressure is the ratio of a force to the area on which the force acts. The SI pressure unit, N/m^2 , is called a pascal (Pa), while in AE is called psi.

Some common nonstandard variations of pressure measurement used with the SI system are

- a. Bars (bar): $100 \text{ kPa} = 1 \text{ bar}$
- b. Kilograms (force) per square centimeter (kg_f/cm^2)*—a very common measure of pressure but not standard in SI (often called just “kilos”)
- c. Torr (Torr): $760 \text{ Torr} = 1 \text{ atm}$

In the AE system pressure can be expressed in a variety of ways, including

- a. Millimeters of mercury (mm Hg)
- b. Inches of mercury (in. Hg)
- c. Feet of water (ft H_2O)
- d. Inches of water (in. H_2O)
- e. Atmospheres (atm)
- f. Pounds (force) per square inch (often called just “pounds”) (psi)

The pressure at the bottom of the static (nonmoving) column of mercury exerted on the sealing plate is:

$$p = \rho gh + p_0$$

Where p = pressure at the bottom of the column of the fluid, ρ = density of fluid, g = acceleration of gravity, h = height of the fluid column, and p_0 = pressure at the top of the column of fluid.

For Example, suppose that the cylinder of fluid in Figure above is a column of mercury that has an area of 1 cm^2 and is 50 cm high. The density of the Hg is 13.55 g/cm^3 . Thus, the force exerted by the mercury alone on the 1 cm^2 section of the bottom plate by the column of mercury is:

$$F = \frac{13.55 \text{ g}}{\text{cm}^3} \left| \frac{980 \text{ cm}}{\text{s}^2} \right| 50 \text{ cm} \left| 1 \text{ cm}^2 \right| \frac{1 \text{ kg}}{1000 \text{ g}} \left| \frac{1 \text{ m}}{100 \text{ cm}} \right| \frac{1 \text{ N s}^2}{1 \text{ kg m}} = 6.64 \text{ N}$$

The pressure on the section of the plate covered by the mercury is the force per unit area of the mercury plus the pressure of the atmosphere:

$$p = \frac{6.64 \text{ N}}{1 \text{ cm}^2} \left| \left(\frac{100 \text{ cm}}{1 \text{ m}} \right)^2 \right| \frac{(1 \text{ m}^2)(1 \text{ Pa})}{1 \text{ N}} \left| \frac{1 \text{ kPa}}{1000 \text{ Pa}} \right| + p_0 = 66.4 \text{ kPa} + p_0$$

If we had started with units in the AE system, the pressure would be computed as [the density of mercury is $845.5 \text{ lb}_m/\text{ft}^3$]:

$$\begin{aligned} p &= \frac{845.5 \text{ lb}_m}{1 \text{ ft}^3} \left| \frac{32.2 \text{ ft}}{\text{s}^2} \right| 50 \text{ cm} \left| \frac{1 \text{ in.}}{2.54 \text{ cm}} \right| \frac{1 \text{ ft}}{12 \text{ in.}} \left| \frac{(\text{s}^2)(\text{lb}_f)}{32.174 (\text{ft})(\text{lb}_m)} \right| \\ &\quad + p_0 \\ &= 1388 \frac{\text{lb}_f}{\text{ft}^2} + p_0 \end{aligned}$$

Pressure, like temperature, can be expressed in either absolute (**psia**) or relative scales. Rather than using the word *relative*, the relative pressure is usually called **gauge pressure** (**psig**). The

atmospheric pressure is nothing more than the **barometric pressure**. The relationship between gauge and absolute pressure is given by the following expression:

$$P_{\text{absolute}} = P_{\text{gauge}} + P_{\text{atmospheric}}$$

$$P_{\text{vacuum}} = P_{\text{atmospheric}} - P_{\text{absolute}}$$

Measurement of Pressure

Pressure, like temperature, can be expressed using either an absolute or a relative scale.

The pressure of the atmosphere can be thought of as the pressure at the base of a column of fluid (air) located at the point of measurement (e.g., at sea level). A typical values are 760 mm Hg and 1 atm.

The relationship between relative and absolute pressure is given by the following expression:

$$\text{Absolute Pressure} = \text{Gauge Pressure} + \text{atmospheric Pressure}$$

The standard atmosphere is equal to

- ◆ 1.00 atmospheres (atm)
- ◆ 33.91 feet of water (ft H₂O)
- ◆ 14.7 pounds (force) per square inch absolute (psia)
- ◆ 29.92 inches of mercury (in. Hg)
- ◆ 760.0 millimeters of mercury (mm Hg)
- ◆ 1.013×10^5 pascal (Pa) or newtons per square meter (N/m²); or 101.3 kPa.

For Example, convert 35 psia to inches of mercury and kPa.

$$35 \text{ psia} \left| \frac{29.92 \text{ in.Hg}}{14.7 \text{ psia}} = 71.24 \text{ in. Hg} \right.$$

$$35 \text{ psia} \left| \frac{101.3 \text{ kPa}}{14.7 \text{ psia}} = 241 \text{ kPa} \right.$$

A manometer is a U-shaped tube partially filled with a fluid of known density (the manometer fluid). Manometers are used in several different ways, as shown in Figure.

- Open-end manometer:** one end is exposed to a fluid whose pressure is to be measured, and the other is open to the atmosphere. This type is used to measure a relative (gauge) pressure.
- Differential manometer:** is used to measure the pressure difference between two points in a process line.
- Sealed-end manometer:** has a near-vacuum enclosed at one end and used to to measure absolute pressure.

Example 20

The pressure gauge on a tank of CO_2 used to fill soda-water bottles reads 51.0 psi. At the same time the barometer reads 28.0 in. Hg. What is the absolute pressure in the tank in psia?

**Solution**

$$\text{Atmospheric pressure} = 28 \text{ in. Hg} \left| \frac{14.7 \text{ psia}}{29.92 \text{ in.Hg}} \right. = 13.76 \text{ psia}$$

The absolute pressure in the tank is

$$51.0 \text{ psia} + 13.76 \text{ psia} = 64.8 \text{ psia}$$
